MCP4821/MCP4822

12-Bit DACs with Internal $V_{\text{REF}}$ and SPI™ Interface

Features

- 12-Bit Resolution
- ±0.2 LSb DNL (typ.)
- ±2 LSb INL (typ.)
- Single or Dual Channel
- Rail-to-Rail Output
- SPI™ Interface with 20 MHz Clock Support
- Simultaneous Latching of the Dual DACs with LDAC pin
- Fast Settling Time of 4.5 µs
- Selectable Unity or 2x Gain Output
- 2.048V Internal Band Gap Voltage Reference
- 50 ppm/°C $V_{\text{REF}}$ Temperature Coefficient
- 2.7V to 5.5V Single-Supply Operation
- Extended Temperature Range: -40°C to +125°C

Applications

- Set Point or Offset Trimming
- Sensor Calibration
- Precision Selectable Voltage Reference
- Portable Instrumentation (Battery-Powered)
- Calibration of Optical Communication Devices

Description

The Microchip Technology Inc. MCP482X devices are 2.7V–5.5V, low-power, low DNL, 12-bit Digital-to-Analog Converters (DACs) with internal band gap voltage reference, optional 2x-buffered output and Serial Peripheral Interface (SPI™).

The MCP482X family of DACs provide high accuracy and low noise performance for industrial applications where calibration or compensation of signals (such as temperature, pressure and humidity) are required.

The MCP482X devices are available in the extended temperature range and PDIP, SOIC and MSOP packages.

The MCP482X devices utilize a resistive string architecture, with its inherent advantages of low DNL error, low ratio metric temperature coefficient and fast settling time. These devices are specified over the extended temperature range. The MCP482X family includes double-buffered registers, allowing simultaneous updates using the LDAC pin. These devices also incorporate a Power-On Reset (POR) circuit to ensure reliable power-up.

Package Types

8-Pin PDIP, SOIC, MSOP

† Notice: Stresses above those listed under “Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

Note 1: By design, not production tested.
2: Too small to quantify.

## Internal Voltage Reference (VREF)

**Nominal Reference Voltage VREF**: 2.008, 2.048, 2.088 V

**Output Voltage (VOUTA when G = 1x and Code = 0xFFFh)**

**Temperature Coefficient (Note 1)**

- ΔVREF/°C
  - -125°C to 0°C: 0.25 ppm/°C
  - 0°C to +85°C: 0.65 ppm/°C

**Output Noise (VREF Noise)**

- E<sub>NREF</sub> (0.1-10 Hz)
  - Code = 0xFFFh, G = 1
- E<sub>NREF</sub> (1 kHz)
  - Code = 0xFFFh, G = 1
- E<sub>NREF</sub> (10 kHz)
  - Code = 0xFFFh, G = 1

**1/f Corner Frequency**

- f<sub>CORNER</sub> — 400 Hz

## Output Amplifier

**Output Swing**

- V<sub>OUT</sub> — 0.010 to V<sub>DD</sub> – 0.040

**Phase Margin**

- PM — 66°

**Slew Rate**

- SR — 0.55 V/µs

**Short Circuit Current**

- I<sub>SC</sub> — 14 mA

**Settling Time**

- t<sub>SETTLING</sub> — 4.5 µs

## Dynamic Performance

**DAC-to-DAC Crosstalk**

- <10 nV-s

**Major Code Transition Glitch**

- 45 nV-s

**Digital Feedthrough**

- <10 nV-s

**Analog Crosstalk**

- <10 nV-s

## 5V Extended Temperature Specifications

**Electrical Specifications**: Unless otherwise indicated, V<sub>DD</sub> = 5V, AV<sub>SS</sub> = 0V, V<sub>REF</sub> = 2.048V, output buffer gain (G) = 2x, R<sub>L</sub> = 5 kΩ to GND, C<sub>L</sub> = 100 pF. Typical values at +125°C by characterization or simulation.

### Power Requirements

**Input Voltage**

- V<sub>DD</sub> — 2.7, 5.5 V

**Input Current - MCP4821**

- IDD — 350 µA

**Hardware Shutdown Current**

- I<sub>SHDN</sub> — 1.5 µA

**Software Shutdown Current**

- I<sub>SHDN_SW</sub> — 5 µA

**Power-On Reset threshold**

- V<sub>POR</sub> — 1.85 V

## DC Accuracy

**Resolution**

- n — 12 Bits

**INL Error**

- INL — ±4 LSb

---

**Notes**:

1. By design, not production tested.
2. Too small to quantify.
### 5V Extended Temperature Specifications (Continued)

**Electrical Specifications:** Unless otherwise indicated, $V_{DD} = 5V$, $AV_{SS} = 0V$, $V_{REF} = 2.048V$, output buffer gain ($G$) = 2x, $R_L = 5 k\Omega$ to GND, $C_L = 100 \mu F$. Typical values at $+125^\circ C$ by characterization or simulation.

3.1 Positive Power Supply Input (\(V_{DD}\))

\(V_{DD}\) is the positive power supply input. The input power supply is relative to AVSS and can range from 2.7V to 5.5V. A decoupling capacitor on \(V_{DD}\) is recommended to achieve maximum performance.

3.2 Chip Select (\(CS\))

\(CS\) is the chip select input, which requires an active-low signal to enable serial clock and data functions.

3.3 Serial Clock Input (SCK)

SCK is the SPI compatible serial clock input.

3.4 Serial Data Input (SDI)

SDI is the SPI compatible serial data input.

3.5 Latch DAC Input (LDAC)

LDAC (the latch DAC synchronization input) transfers the input latch registers to the DAC registers (output latches) when low. Can also be tied low if transfer on the rising edge of \(CS\) is desired.

3.6 Hardware Shutdown Input (\(SHDN\))

\(SHDN\) is the hardware shutdown input that requires an active-low input signal to configure the DACs in their low-power Standby mode.

3.7 DACx Outputs (\(VOUTA, VOUTB\))

\(VOUTA\) and \(VOUTB\) are DAC outputs. The DAC output amplifier drives these pins with a range of AVSS to \(V_{DD}\).

3.8 Analog Ground (AVSS)

AVSS is the analog ground pin.
4.0 GENERAL OVERVIEW

The MCP482X devices are voltage-output string DACs. These devices include rail-to-rail output amplifiers, internal voltage reference, shutdown and reset-management circuitry. Serial communication conforms to the SPI protocol. The MCP482X devices operate from 2.7V to 5.5V supplies.

The coding of these devices is straight binary, with the ideal output voltage given by Equation 4-1, where \( G \) is the selected gain (1x or 2x), \( D_N \) represents the digital input value and \( n \) represents the number of bits of resolution (\( n = 12 \)).

\[
V_{OUT} = \frac{2.048V \cdot G \cdot D_N}{2^n}
\]

1 LSb is the ideal voltage difference between two successive codes. Table 4-1 illustrates how to calculate LSb.

4.0.1 INL ACCURACY

INL error for these devices is the maximum deviation between an actual code transition point and its corresponding ideal transition point once offset and gain errors have been removed. These endpoints are from 0x000 to 0xFFF. Refer to Figure 4-1.

Positive INL represents transition(s) later than ideal. Negative INL represents transition(s) earlier than ideal.

4.0.2 DNL ACCURACY

DNL error is the measure of variations in code widths from the ideal code width. A DNL error of zero would imply that every code is exactly 1 LSb wide.

4.0.3 OFFSET ERROR

Offset error is the deviation from zero voltage output when the digital input code is zero.

4.0.4 GAIN ERROR

Gain error is the deviation from the ideal output, \( V_{REF} - 1 \) LSb, excluding the effects of offset error.
4.1 Circuit Descriptions

4.1.1 OUTPUT AMPLIFIERS
The DACs’ outputs are buffered with a low-power, precision CMOS amplifier. This amplifier provides low offset voltage and low noise. The output stage enables the device to operate with output voltages close to the power supply rails. Refer to Section 1.0 “Electrical Characteristics” for range and load conditions.

In addition to resistive load-driving capability, the amplifier will also drive high capacitive loads without oscillation. The amplifiers’ strong outputs allow $V_{OUT}$ to be used as a programmable voltage reference in a system.

4.1.1.1 Programmable Gain Block
The rail-to-rail output amplifier has configurable gain, allowing optimal full-scale outputs for differing voltage reference inputs. The output amplifier gain has two selections, a gain of 1 V/V ($G_A = 1$) or a gain of 2 V/V ($G_A = 0$).

The output range is ideally 0.000V to 4095/4096 * 2.048V when $G = 1$, and 0.000 to 4095/4096 * 4.096V when $G = 2$. The default value for this bit is a gain of 2, yielding an ideal full-scale output of 0.000V to 4.096V due to the internal 2.048V $V_{REF}$. Note that the near rail-to-rail CMOS output buffer’s ability to approach $AV_{SS}$ and $V_{DD}$ establish practical range limitations. The output swing specification in Section 1.0 “Electrical Characteristics” defines the range for a given load condition.

4.1.2 VOLTAGE REFERENCE
The MCP482X devices utilize internal 2.048V voltage reference. The voltage reference has low temperature coefficient and low noise characteristics. Refer to Section 1.0 “Electrical Characteristics” for the voltage reference specifications.

4.1.3 POWER-ON RESET CIRCUIT
The Power-On Reset (POR) circuit ensures that the DACs power-up with $SHDN = 0$ (high-impedance). The devices will continue to have a high-impedance output until a valid Write command is performed to either of the DAC registers and the LDAC pin meets the input low threshold.

If the power supply voltage is less than the POR threshold ($V_{POR} = 2.0V$, typical), the DACs will be held in their reset state. They will remain in that state until $V_{DD} > V_{POR}$ and a subsequent Write command is received.

Figure 4-3 shows a typical power supply transient pulse and the duration required to cause a reset to occur, as well as the relationship between the duration and trip voltage. A 0.1 $\mu$F decoupling capacitor, mounted as close as possible to the $V_{DD}$ pin, provides additional transient immunity.

4.1.4 SHUTDOWN MODE
Shut down mode can be entered by using either hardware or software commands. The hardware pin (SHDN) is only available on the MCP4821. During Shutdown mode, the supply current is isolated from most of the internal circuitry. The serial interface remains active, thus allowing a Write command to bring the device out of Shutdown mode. When the output amplifiers are shut down, the feedback resistance (typically 500 k$\Omega$) produces a high-impedance path to $AV_{SS}$. The device will remain in Shutdown mode until the $SHDN$ pin is brought high and a write command with $SD = 1$ is latched into the device. When a DAC is changed from Shutdown to Active mode, the output settling time takes $< 10 \mu$s, but greater than the standard Active mode settling time ($4.5 \mu$s).
5.0 SERIAL INTERFACE

5.1 Overview

The MCP482X family is designed to interface directly with the SPI port, available on many microcontrollers, and supports Mode 0,0 and Mode 1,1. Commands and data are sent to the device via the SDI pin, with data being clocked-in on the rising edge of SCK. The communications are unidirectional and, thus, data cannot be read out of the MCP482X devices. The CS pin must be held low for the duration of a write command. The write command consists of 16 bits and is used to configure the DAC's control and data latches. Register 5-1 details the input registers used to configure and load the DAC_A and DAC_B registers. Refer to Figure 1-1 and the AC Electrical Characteristics tables for detailed input and output timing specifications for both Mode 0,0 and Mode 1,1 operation.

5.2 Write Command

The write command is initiated by driving the CS pin low, followed by clocking the four configuration bits and the 12 data bits into the SDI pin on the rising edge of SCK. The CS pin is then raised, causing the data to be latched into the selected DAC's input registers. The MCP482X devices utilize a double-buffered latch structure to allow both DAC_A's and DAC_B's outputs to be synchronized with the LDAC pin, if desired. Upon the LDAC pin achieving a low state, the values held in the DAC's input registers are transferred into the DACs' output registers. The outputs will transition to the value and held in the DAC_X register.

All writes to the MCP482X devices are 16-bit words. Any clocks past 16 will be ignored. The most significant four bits are configuration bits. The remaining 12 bits are data bits. No data can be transferred into the device with CS high. This transfer will only occur if 16 clocks have been transferred into the device. If the rising edge of CS occurs prior, shifting of data into the input registers will be aborted.

6.0 TYPICAL APPLICATIONS

The MCP482X devices are general purpose DACs intended to be used in applications where a precision, low-power DAC with moderate bandwidth and internal voltage reference is required.

Applications generally suited for the MCP482X devices include:

- Set Point or Offset Trimming
- Sensor Calibration
- Precision Selectable Voltage Reference
- Portable Instrumentation (Battery-Powered)
- Calibration of Optical Communication Devices

6.1 Digital Interface

The MCP482X devices utilize a 3-wire synchronous serial protocol to transfer the DACs' setup and output values from the digital source. The serial protocol can be interfaced to SPI™ or Microwire peripherals common on many microcontroller units (MCUs), including Microchip's PICmicro® MCUs and dsPIC® DSC family of MCUs. In addition to the three serial connections (CS, SCK and SDI), the LDAC signal synchronizes when the serial settings are latched into the DAC's output from the serial input latch. Figure 6-1 illustrates the required connections. Note that LDAC is active-low. If desired, this input can be tied low to reduce the required connections from 4 to 3. Write commands will be latched directly into the output latch when a valid 16 clock transmission has been received and CS has been raised.

6.2 Power Supply Considerations

The typical application will require a bypass capacitor in order to filter high-frequency noise. The noise can be induced onto the power supply's traces or as a result of changes on the DAC's output. The bypass capacitor helps to minimize the effect of these noise sources on signal integrity. Figure 6-1 illustrates an appropriate bypass strategy.

In this example, the recommended bypass capacitor value is 0.1 µF. This capacitor should be placed as close to the device power pin (VDD) as possible (within 4 mm).

The power source supplying these devices should be as clean as possible. If the application circuit has separate digital and analog power supplies, AVDD and AVSS should reside on the analog plane.

6.3 Output Noise Considerations

The voltage noise density (in µV/√Hz) is illustrated in Figure 2-9. This noise appears at VOUTX and is primarily a result of the internal reference voltage. Its 1/f corner (fCORNER) is approximately 400 Hz.

Figure 2-10 illustrates the voltage noise (in mV RMS or mV P-P). A small bypass capacitor on VOUTX is an effective method to produce a single-pole Low-Pass Filter (LPF) that will reduce this noise. For instance, a bypass capacitor sized to produce a 1 kHz LPF would result in an ENREF of about 100 µV RMS. This would be necessary when trying to achieve the low DNL performance (at G = 1) that the MCP482X devices are capable of. The tested range for stability is .001 µF thru 4.7 µF.

6.4 Layout Considerations

Inductively-coupled AC transients and digital switching noise can degrade the output signal integrity, potentially masking the MCP482X family's performance. Careful board layout will minimize these effects and increase the Signal-to-Noise Ratio (SNR). Bench testing has shown that a multi-layer board utilizing a low-inductance ground plane, isolated inputs, isolated outputs and proper decoupling are critical to achieving the performance that the MCP482X devices are capable of providing. Particularly harsh environments may require shielding of critical signals. Breadboards and wire-wrapped boards are not recommended if low noise is desired.
6.5 Single-Supply Operation

The MCP482X devices are Rail-to-Rail (R-R) input and output DACs designed to operate with a $V_{DD}$ range of 2.7V to 5.5V. Its output amplifier is robust enough to drive common, small-signal loads directly, thus eliminating the cost and size of an external buffer for most applications.

6.5.1 DC SET POINT OR CALIBRATION

A common application for a DAC with the MCP482X family’s performance is a digitally-controlled set point and/or calibration of variable parameters, such as sensor offset or slope. 12-bit resolution provides 4096 output steps. If $G = 1$ is selected, then the internal 2.048 $V_{REF}$ would produce 500 µV of resolution. If $G = 2$ is selected, the internal 2.048 $V_{REF}$ would produce 1 mV of resolution.

6.5.1.1 Decreasing The Output Step Size

If the application is calibrating the threshold of a diode, transistor or resistor tied to $AV_{SS}$, a threshold range of 0.8V may be desired to provide 200 µV resolution. Two common methods to achieve a 0.8V range is to either reduce $V_{REF}$ to 0.82V (would require MCP492X device and external voltage reference) or use a voltage divider on the DAC’s output. Typically, when using a low-voltage $V_{REF}$, the noise floor causes SNR error that is intolerable. The voltage divider method provides some advantages when $V_{REF}$ needs to be very low or when the desired output voltage is not available. Using two resistors to scale the output range down to the precise desired level is a simple, low-cost method to achieve very small step sizes. Example 6-1 illustrates this concept. Note that the bypass capacitor on the output of the voltage divider plays a critical function in attenuating the output noise of the DAC and the induced noise from the environment.

The MCP482X family’s low ±0.75 (max.) DNL performance is critical to meeting calibration accuracy in production.

**EXAMPLE 6-1:** Set Point or Threshold Calibration.

\[
\begin{align*}
V_{OUT} &= 2.048 \cdot G \frac{D}{I_2} \\
V_{trip} &= V_{OUT} \left( \frac{R_2}{R_1 + R_2} \right)
\end{align*}
\]

$G = \text{Gain select (1x or 2x)}$

$D = \text{Digital value of DAC (0 – 4096)}$
6.5.1.2 Building a “Window” DAC

When calibrating a set point or threshold of a sensor, rarely does the sensor utilize the entire output range of the DAC. If the LSB size is adequate to meet the application’s accuracy needs, the resolution is sacrificed without consequences. If greater accuracy is needed, then the output range will need to be reduced to increase the resolution around the desired threshold. If the threshold is not near \( V_{\text{REF}} \), \( 2V_{\text{REF}} \) or \( AV_{\text{SS}} \), then creating a “window” around the threshold has several advantages. One simple method to create this “window” is to use a voltage divider network with a pull-up and pull-down resistor. Example 6-2 and Example 6-4 illustrates this concept.

The MCP482X family’s low ±0.75 (max.) DNL performance is critical to meet calibration accuracy in production.

**EXAMPLE 6-2:** Single-Supply “Window” DAC.

\[
V_{\text{OUT}} = 2.048 \cdot \frac{G \cdot D}{2^{15}}
\]

\( G = \) Gain select (1x or 2x)
\( D = \) Digital value of DAC (0 – 4096)

**Thevenin Equivalent**

\[
\begin{align*}
R_{23} &= \frac{R_2 \cdot R_3}{R_2 + R_3} \\
V_{23} &= \frac{(V_{\text{CC}+} \cdot R_2) + (V_{\text{CC}-} \cdot R_3)}{R_2 + R_3} \\
V_{\text{trip}} &= \frac{V_{\text{OUT}} \cdot R_{23} + V_{23} \cdot R_1}{R_2 + R_{23}}
\end{align*}
\]
6.6 Bipolar Operation

Bipolar operation is achievable using the MCP482X devices by using an external operational amplifier (op amp). This configuration is desirable due to the wide variety and availability of op amps. This allows a general purpose DAC, with its cost and availability advantages, to meet almost any desired output voltage range, power and noise performance.

Example 6-3 illustrates a simple bipolar voltage source configuration. \( R_1 \) and \( R_2 \) allow the gain to be selected, while \( R_3 \) and \( R_4 \) shift the DAC’s output to a selected offset. Note that \( R_4 \) can be tied to \( V_{DD} \), instead of \( AV_{SS} \), if a higher offset is desired. Note that a pull-up to \( V_{DD} \) could be used, instead of \( R_4 \) or in addition to \( R_4 \), if a higher offset is desired.

\[
\begin{align*}
V_{OUT} &= 2.048 \cdot G \frac{D}{2^{12}} \\
V_{IN+} &= \frac{V_{OUT} \cdot R_4}{R_3 + R_4} \\
V_O &= V_{IN+} \left( 1 + \frac{R_2}{R_1} \right) - V_{DD} \left( \frac{R_2}{R_1} \right)
\end{align*}
\]

**EXAMPLE 6-3:** Digitally-Controlled Bipolar Voltage Source.

### 6.6.1 DESIGN A BIPOLAR DAC USING EXAMPLE 6-3

An output step magnitude of 1 mV, with an output range of ±2.05V, is desired for a particular application.

1. Calculate the range: +2.05V – (-2.05V) = 4.1V.
2. Calculate the resolution needed:
   \[
   4.1V/1 \text{ mV} = 4100
   \]
   Since \( 2^{12} = 4096 \), 12-bit resolution is desired.
3. The amplifier gain (\( R_2 / R_1 \)), multiplied by full-scale \( V_{OUT} \) (4.096V), must be equal to the desired minimum output to achieve bipolar operation. Since any gain can be realized by choosing resistor values (\( R_1 + R_2 \)), the \( V_{REF} \) value must be selected first. If a \( V_{REF} \) of 4.096V is used (\( G = 2 \)), solve for the amplifier’s gain by setting the DAC to 0, knowing that the output needs to be -2.05V. The equation can be simplified to:

\[
-\frac{R_2}{R_1} = \frac{-2.05}{4.096} \quad \frac{R_2}{R_1} = \frac{1}{2}
\]

If \( R_1 = 20 \text{ kΩ} \) and \( R_2 = 10 \text{ kΩ} \), the gain will be 0.5

4. Next, solve for \( R_3 \) and \( R_4 \) by setting the DAC to 4096, knowing that the output needs to be +2.05V.

\[
\frac{R_4}{R_3 + R_4} = \frac{2.05V + (0.5 \cdot 4.096V)}{1.5 \cdot 4.096V} = \frac{2}{3}
\]

If \( R_4 = 20 \text{ kΩ} \), then \( R_3 = 10 \text{ kΩ} \)
6.7 Selectable Gain and Offset Bipolar Voltage Output Using A Dual DAC

In some applications, precision digital control of the output range is desirable. Example 6-4 illustrates how to use the MCP482X family to achieve this in a bipolar or single-supply application.

This circuit is typically used for linearizing a sensor whose slope and offset varies.

The equation to design a bipolar “window” DAC would be utilized if $R_3$, $R_4$ and $R_5$ are populated.

---

**EXAMPLE 6-4:** Bipolar Voltage Source with Selectable Gain and Offset.

![Diagram of MCP482X with equations]

$$V_{OUTB} = \left(2.048V \cdot G_B\right)\frac{D_B}{2^{12}}$$

$$V_{OUTA} = \left(2.048V \cdot G_A\right)\frac{D_A}{2^{12}}$$

$$V_{IN+} = \frac{V_{OUTB} R_4 + V_{CC} R_3}{R_3 + R_4}$$

$$V_O = V_{IN+} \left(1 + \frac{R_3}{R_4}\right) - V_{OUTA} \left(\frac{R_3}{R_4}\right)$$

Thevenin Equivalent

$$V_{45} = \frac{V_{CC} R_4 + V_{CC} R_5}{R_4 + R_5}$$

$$R_{45} = \frac{R_4 R_5}{R_4 + R_5}$$

$$V_{IN+} = \frac{V_{OUTB} R_{45} + V_{45} R_3}{R_3 + R_{45}}$$

$$V_O = V_{IN+} \left(1 + \frac{R_3}{R_4}\right) - V_{OUTA} \left(\frac{R_3}{R_4}\right)$$

Offset Adjust  Gain Adjust
6.8 Designing A Double-Precision DAC Using A Dual DAC

Example 6-5 illustrates how to design a single-supply voltage output capable of up to 24-bit resolution from a dual 12-bit DAC. This design is simply a voltage divider with a buffered output.

As an example, if a similar application to the one developed in Section 6.6.1 “Design a Bipolar DAC Using Example 6-3” required a resolution of 1 µV instead of 1 mV, and a range of 0V to 4.1V, then 12-bit resolution would not be adequate.

1. Calculate the resolution needed:
4.1V/1 µV = 4.1e06. Since $2^{22} = 4.2e06$, 22-bit resolution is desired. Since DNL = ±0.75 LSb, this design can be attempted with the MCP482X family.

2. Since DACB’s VOUTB has a resolution of 1 mV, its output only needs to be “pulled” 1/1000 to meet the 1 µV target. Dividing VOUTA by 1000 would allow the application to compensate for DACB’s DNL error.

3. If $R_2$ is 100Ω, then $R_1$ needs to be 100 kΩ.

4. The resulting transfer function is shown in the equation of Example 6-5.

$$V_{O} = \frac{V_{OUTA}R_2 + V_{OUTB}R_1}{R_1 + R_2}$$

$$V_{OUTA} = 2.048V \cdot G \frac{D_A}{2^{12}} \quad V_{OUTB} = 2.048V \cdot G \frac{D_B}{2^{12}}$$

$G =$ Gain select (1x or 2x)
$D =$ Digital value of DAC (0 – 4096)

**EXAMPLE 6-5:** Simple, Double-Precision DAC.
6.9 Building A Programmable Current Source

Example 6-6 illustrates a variation on a voltage follower design where a sense resistor is used to convert the DAC's voltage output into a digitally-selectable current source.

Adding the resistor network from Example 6-2 would be advantageous in this application. The smaller $R_{\text{SENSE}}$ is, the less power dissipated across it. However, this also reduces the resolution that the current can be controlled with. The voltage divider, or “window”, DAC configuration would allow the range to be reduced, thus increasing resolution around the range of interest. When working with very small sensor voltages, plan on eliminating the amplifier's offset error by storing the DAC's setting under known sensor conditions.

$$V_{\text{OUT}} = 2.048V \cdot \frac{G}{2^{12}}$$

$$I_b = \frac{I_L}{\beta}$$

$$I_L = \frac{V_{\text{OUT}}}{R_{\text{SENSE}}} \times \frac{\beta}{\beta + 1}$$

$G =$ Gain select (1x or 2x)
$D =$ Digital value of DAC (0 – 4096)

**EXAMPLE 6-6:** Digitally-Controlled Current Source.
7.0 DEVELOPMENT SUPPORT

7.1 Evaluation & Demonstration Boards
The Mixed Signal PICtail™ Demo Board supports the MCP482X family of devices. Refer to www.microchip.com for further information on this product's capabilities and availability.

7.2 Application Notes
Application notes illustrating the performance and implementation of the MCP482X family are planned but are currently not released. Refer to www.microchip.com for further information.

Y  Year code (last digit of calendar year)  
YY  Year code (last 2 digits of calendar year)  
WW  Week code (week of January 1 is week '01')  
NNN  Alphanumeric traceability code  
\( e\vphantom{3} \)  Pb-free JEDEC designator for Matte Tin (Sn)  
*  This package is Pb-free. The Pb-free JEDEC designator \( (e\vphantom{3}) \) can be found on the outer packaging for this package.

Note:  
In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.

Device:  
MCP4821: 12-Bit DAC with SPI™ Interface  
MCP4821T: 12-Bit DAC with SPI Interface  
(Tape and Reel) (SOIC, MSOP)  
MCP4822: 12-Bit DAC with SPI Interface  
MCP4822T: 12-Bit DAC with SPI Interface  
(Tape and Reel) (SOIC, MSOP)

Temperature Range: E = -40°C to +125°C

Package:  
MS = Plastic MSOP, 8-lead  
P = Plastic DIP (300 mil Body), 8-lead  
SN = Plastic SOIC, (150 mil Body), 8-lead

Examples:

a) MCP4821T-E/SN: Tape and Reel  
   Extended Temperature,  
   8LD SOIC package.

b) MCP4821T-E/MS: Tape and Reel  
   Extended Temperature,  
   8LD MSOP package.

c) MCP4821-E/SN: Extended Temperature,  
   8LD SOIC package.

d) MCP4821-E/MS: Extended Temperature,  
   8LD MSOP package.

e) MCP4821-E/P: Extended Temperature,  
   8LD PDIP package.

a) MCP4822T-E/SN: Tape and Reel  
   Extended Temperature,  
   8LD SOIC package.

b) MCP4822-E/P: Extended Temperature,  
   8LD PDIP package.

c) MCP4822-E/SN: Extended Temperature,  
   8LD SOIC package.
Note the following details of the code protection feature on Microchip devices:

• Microchip products meet the specification contained in their particular Microchip Data Sheet.

• Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.

• There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.

• Microchip is willing to work with the customer who is concerned about the integrity of their code.

• Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip’s products as critical components in life support systems is not authorized except with express written approval by Microchip. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Quality Management System Certified by DNV

ISO/TS 16949:2002

Microchip received ISO/TS-16949:2002 quality system certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona and Mountain View, California in October 2003. The Company’s quality system processes and procedures are for its PICmicro® 8-bit MCUs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
