Preface

Welcome to the MSP430 IAR Assembler Reference Guide. The purpose of this guide is to provide you with detailed reference information that can help you to use the MSP430 IAR Assembler to develop your application according to your requirements.

Who should read this guide

You should read this guide if you plan to develop an application, or part of an application, using assembler language for the MSP430 microcontroller and need to get detailed reference information on how to use the MSP430 IAR Assembler. In addition, you should have working knowledge of the following:

- The architecture and instruction set of the MSP430 microcontroller. Refer to the documentation from Texas Instruments for information about the MSP430 microcontroller
- General assembler language programming
- Application development for embedded systems
- The operating system of your host machine.

How to use this guide

When you first begin using the MSP430 IAR Assembler, you should read the Introduction to the MSP430 IAR Assembler chapter in this reference guide.

If you are an intermediate or advanced user, you can focus more on the reference chapters that follow the introduction.

If you are new to using the IAR toolkit, we recommend that you first read the initial chapters of the MSP430 IAR Embedded Workbench™ IDE User Guide. They give product overviews, as well as tutorials that can help you get started.
What this guide contains

Below is a brief outline and summary of the chapters in this guide.

- *Introduction to the MSP430 IAR Assembler* provides programming information. It also describes the source code format, and the format of assembler listings.
- *Assembler options* first explains how to set the assembler options from the command line and how to use environment variables. It then gives an alphabetical summary of the assembler options, and contains detailed reference information about each option.
- *Assembler operators* gives a summary of the assembler operators, arranged in order of precedence, and provides detailed reference information about each operator.
- *Assembler directives* gives an alphabetical summary of the assembler directives, and provides detailed reference information about each of the directives, classified into groups according to their function.
- *Diagnostics* contains information about the formats and severity levels of diagnostic messages.

Other documentation

The complete set of IAR Systems development tools for the MSP430 microcontroller is described in a series of guides. For information about:

- Using the IAR Embedded Workbench™ and the IAR C-SPY™ Debugger, refer to the *MSP430 IAR Embedded Workbench™ IDE User Guide*.
- Programming for the MSP430 IAR C/EC++ Compiler, refer to the *MSP430 IAR C/EC++ Compiler Reference Guide*.
- Using the IAR XLINK Linker™, the IAR XLIB Librarian™, and the IAR XAR Library Builder™, refer to the *IAR Linker and Library Tools Reference Guide*.
- Using the IAR C Library, refer to the *IAR C Library Functions Reference Guide*, available from the IAR Embedded Workbench IDE Help menu.
- Using the Embedded C++ Library, refer to the *C++ Library Reference*, available from the IAR Embedded Workbench IDE Help menu.

All of these guides are delivered in PDF format on the installation media. Some of them are also delivered as printed books.
# Document conventions

This guide uses the following typographic conventions:

<table>
<thead>
<tr>
<th>Style</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>computer</td>
<td>Text that you enter or that appears on the screen.</td>
</tr>
<tr>
<td>parameter</td>
<td>A label representing the actual value you should enter as part of a command.</td>
</tr>
<tr>
<td>[option]</td>
<td>An optional part of a command.</td>
</tr>
<tr>
<td>{a</td>
<td>b</td>
</tr>
<tr>
<td><strong>bold</strong></td>
<td>Names of menus, menu commands, buttons, and dialog boxes that appear on the screen.</td>
</tr>
<tr>
<td>reference</td>
<td>A cross-reference within this or to another guide.</td>
</tr>
<tr>
<td>![icon]</td>
<td>Identifies instructions specific to the IAR Embedded Workbench interface.</td>
</tr>
<tr>
<td>![icon]</td>
<td>Identifies instructions specific to the command line interface.</td>
</tr>
</tbody>
</table>

*Table 1: Typographic conventions used in this guide*
Introduction to the MSP430 IAR Assembler

This chapter describes the syntax conventions and source code format for the MSP430 IAR Assembler and provides programming hints.

Refer to Texas Instruments' hardware documentation for syntax descriptions of the instruction mnemonics.

Syntax conventions

In the syntax definitions the following conventions are used:

- Parameters, representing what you would type, are shown in italics. So, for example, in:
  
  `ORG expr`

  `expr` represents an arbitrary expression.

- Optional parameters are shown in square brackets. So, for example, in:
  
  `END [expr]`

  The `expr` parameter is optional. An ellipsis indicates that the previous item can be repeated an arbitrary number of times. For example:

  `PUBLIC symbol [,symbol] ...`

  Indicates that `PUBLIC` can be followed by one or more symbols, separated by commas.

- Alternatives are enclosed in { and } brackets, separated by a vertical bar, for example:

  `LSTOUT{+| -}`

  Indicates that the directive must be followed by either + or -.

LABELS AND COMMENTS

Where a label must precede a directive, this is indicated in the syntax, as in:

`label1 VAR expr`

An optional label, which will assume the value and type of the current program location counter (PLC), can precede all directives. For clarity, this is not included in each syntax definition.
In addition, unless explicitly specified, all directives can be followed by a comment, preceded by ; (semicolon).

**PARAMETERS**

The following table shows the correct form of the most commonly used types of parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>What it consists of</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr</td>
<td>An expression; see Assembler expressions, page 4.</td>
</tr>
<tr>
<td>label</td>
<td>A symbolic label.</td>
</tr>
<tr>
<td>symbol</td>
<td>An assembler symbol.</td>
</tr>
</tbody>
</table>

Table 2: Assembler directive parameters

The format of an assembler source line is as follows:

```
[label [:]] [operation] [operands] [ ; comment]
```

where the components are as follows:

- **label**: A label, which is assigned the value and type of the current program location counter (PLC). The ; (colon) is optional if the label starts in the first column.
- **operation**: An assembler instruction or directive. This must not start in the first column.
- **operands**: An assembler instruction can have zero, one, or more operands. The data definition directives, for example DB and DC8, can have any number of operands. For reference information about the data definition directives, see Data definition or allocation directives, page 73.
  
  Other assembler directives can have one, two, or three operands, separated by commas.
- **comment**: Comment, preceded by a ; (semicolon)
  
  Use /* ... */ to comment sections
  
  Use // to mark the rest of the line as comment.

The fields can be separated by spaces or tabs.

A source line may not exceed 2047 characters.
Tab characters, ASCII 09H, are expanded according to the most common practice; i.e. to columns 8, 16, 24 etc.

The MSP430 IAR Assembler uses the default filename extensions .s43, .asm, and .msa for source files.

List file format

The format of an assembler list file is as follows:

**HEADER**

The header section contains product version information, the date and time when the file was created, and which options were used.

**BODY**

The body of the listing contains the following fields of information:

- The line number in the source file. Lines generated by macros will, if listed, have a . (period) in the source line number field.
- The address field shows the location in memory, which can be absolute or relative depending on the type of segment. The notation is hexadecimal.
- The data field shows the data generated by the source line. The notation is hexadecimal. Unresolved values are represented by ..... (periods), where two periods signify one byte. These unresolved values will be resolved during the linking process.
- The assembler source line.

**SUMMARY**

The end of the file contains a summary of errors and warnings that were generated, and a checksum (CRC).

**Note:** The CRC number depends on the date when the source file was assembled.

**SYMBOL AND CROSS-REFERENCE TABLE**

When you specify the Include cross-reference option, or if the LSTXRF+ directive has been included in the source file, a symbol and cross-reference table is produced.

The following information is provided for each symbol in the table:

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>The label's user-defined name.</td>
</tr>
</tbody>
</table>

*Table 3: Symbol and cross-reference table*
Assembler expressions

Expressions consist of operands and operators.

The assembler will accept a wide range of expressions, including both arithmetic and logical operations. All operators use 32-bit two’s complement integers, and the range is only checked when a value is used for generating code.

Expressions are evaluated from left to right, unless this order is overridden by the priority of operators; see also Precedence of operators, page 25.

The following operands are valid in an expression:
- User-defined symbols and labels.
- Constants, excluding floating-point constants.
- The program location counter (PLC) symbol, $.

These are described in greater detail in the following sections.

The valid operators are described in the chapter Assembler operators, page 25.

TRUE AND FALSE

In expressions a zero value is considered FALSE, and a non-zero value is considered TRUE.

Conditional expressions return the value 0 for FALSE and 1 for TRUE.

USING SYMBOLS IN RELOCATABLE EXPRESSIONS

Expressions that include symbols in relocatable segments cannot be resolved at assembly time, because they depend on the location of the segments.

Such expressions are evaluated and resolved at link time, by the IAR XLINK Linker™.

There are no restrictions on the expression; any operator can be used on symbols from any segment, or any combination of segments.

<table>
<thead>
<tr>
<th>Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode</td>
<td>ABS (Absolute), or REL (Relative).</td>
</tr>
<tr>
<td>Type</td>
<td>The label type.</td>
</tr>
<tr>
<td>Segment</td>
<td>The name of the segment that this label is defined relative to.</td>
</tr>
<tr>
<td>Value/Offset</td>
<td>The value (address) of the label within the current module, relative to the beginning of the current segment part.</td>
</tr>
</tbody>
</table>

Table 3: Symbol and cross-reference table (Continued)
For example, a program could define the segments DATA and CODE as follows:

```
NAME    prog1
EXTERN  third
RSEG    DATA
first:  DC8     5
second: DC8     3
ENDMOD
MODULE  prog2
RSEG    CODE
start   ...
```

Then in the segment CODE the following relocatable expressions are legal:

```
DC8     first
DC8     first+1
DC8     1+first
DC8     (first/second)*third
```

**Note:** At assembly time, there will be no range check. The range check will occur at link time and, if the values are too large, there will be a linker error.

### SYMBOLS

User-defined symbols can be up to 255 characters long, and all characters are significant.

Symbols must begin with a letter, a–z or A–Z, ? (question mark), or _ (underscore). Symbols can include the digits 0–9 and $ (dollar).

For built-in symbols like instructions, registers, operators, and directives case is insignificant. For user-defined symbols case is by default significant but can be turned on and off using the `Case sensitive user symbols (-s)` assembler option. See page 20 for additional information.

Notice that symbols and labels are byte addresses. For additional information, see `Generating lookup table`, page 75.

### LABELS

Symbols used for memory locations are referred to as labels.

### Program location counter (PLC)

The assembler keeps track of the address of the current instruction. This is called the program location counter.
If you need to refer to the program location counter in your assembler source code you can use the $ sign. For example:

```
BR $ ; Loop forever
```

**INTEGER CONSTANTS**

Since all IAR Systems assemblers use 32-bit two’s complement internal arithmetic, integers have a (signed) range from \(-2^{31}\) to \(2^{31}\).

Constants are written as a sequence of digits with an optional - (minus) sign in front to indicate a negative number.

Commas and decimal points are not permitted.

The following types of number representation are supported:

<table>
<thead>
<tr>
<th>Integer type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>1010b, b'1010'</td>
</tr>
<tr>
<td>Octal</td>
<td>1234q, q'1234'</td>
</tr>
<tr>
<td>Decimal</td>
<td>1234, -1, d'1234'</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>0xFFFFh, 0xFFFF, h'FFFF'</td>
</tr>
</tbody>
</table>

*Table 4: Integer constant formats*

**Note:** Both the prefix and the suffix can be written with either uppercase or lowercase letters.

**ASCII CHARACTER CONSTANTS**

ASCII constants can consist of between zero and more characters enclosed in single or double quotes. Only printable characters and spaces may be used in ASCII strings. If the quote character itself is to be accessed, two consecutive quotes must be used:

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>“ABCD”</td>
<td>ABCD (four characters).</td>
</tr>
<tr>
<td>&quot;ABCD&quot;</td>
<td>ABCD&quot;'O' (five characters the last ASCII null).</td>
</tr>
<tr>
<td>‘A’B’</td>
<td>A'B</td>
</tr>
<tr>
<td>‘’ ‘’ ‘’ (4 quotes)</td>
<td>'</td>
</tr>
<tr>
<td>‘’ (2 quotes)</td>
<td>Empty string (no value).</td>
</tr>
<tr>
<td>“” (2 double quotes)</td>
<td>Empty string (an ASCII null character).</td>
</tr>
<tr>
<td>‘‘ ‘’ ‘’ (4 double quotes)</td>
<td>, for quote within a string, as in ‘I’d love to’</td>
</tr>
</tbody>
</table>

*Table 5: ASCII character constant formats*
FLOATING-POINT CONSTANTS

The MSP430 IAR Assembler will accept floating-point values as constants and convert them into IEEE single-precision (signed 32-bit) floating-point format or fractional format.

Floating-point numbers can be written in the format:

\[ \pm [\text{digits}] . [\text{digits}] \{ [E|e] \pm [\text{digits}] \} \]

Spaces and tabs are not allowed in floating-point constants.

Note: Floating-point constants will not give meaningful results when used in expressions.

The MSP430 single and double precision floating point format

The MSP430 IAR Assemble supports the single and double precision floating point format of Texas Instruments. For a description of this format, see the MSP430 documentation provided by Texas Instruments.

PREDEFINIED SYMBOLS

The MSP430 IAR Assembler defines a set of symbols for use in assembler source files. The symbols provide information about the current assembly, allowing you to test them in preprocessor directives or include them in the assembled code. The strings returned by the assembler are enclosed in double quotes.
The following predefined symbols are available:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DATE</strong></td>
<td>Current date in dd/Mmm/yyyy format (string).</td>
</tr>
<tr>
<td><strong>FILE</strong></td>
<td>Current source filename (string).</td>
</tr>
<tr>
<td><strong>IAR_SYSTEMS_ASM</strong></td>
<td>IAR assembler identifier (number).</td>
</tr>
<tr>
<td><strong>LINE</strong></td>
<td>Current source line number (number).</td>
</tr>
<tr>
<td><strong>TID</strong></td>
<td>Target identity, consisting of two bytes (number). The high byte is the target identity, which is 43 for A430.</td>
</tr>
<tr>
<td><strong>TIME</strong></td>
<td>Current time in hh:mm:ss format (string).</td>
</tr>
<tr>
<td><strong>VER</strong></td>
<td>Version number in integer format; for example, version 4.17 is returned as 417 (number).</td>
</tr>
</tbody>
</table>

Notice that the symbol __TID__ in the assembler is related to the predefined symbol __TID__ in the MSP430 IAR C/EC++ Compiler. It is described in the MSP430 IAR C/EC++ Compiler Reference Guide.

Including symbol values in code

To include a symbol value in the code, several data definition directives are provided. These directives define values or reserve memory. You define a symbol using the appropriate data definition directive.

For example, to include the time of assembly as a string for the program to display:

```assembly
TIM DC8 ___TIME__ ; Time string
...
MOV tim,R4 ; Load address of string
CALL printstr ; Call string output routine
```

For details of each data definition directive, see Data definition or allocation directives, page 73.

Testing symbols for conditional assembly

To test a symbol at assembly time, you can use one of the provided conditional assembly directives. These directives let you control the assembly process at assembly time.
For example, in a source file written for any processor, you may want to assemble, and verify the code for the MSP430 processor. You could do this using the \_TID\_ symbol as follows:

```c
#define TARGET ((__TID__ >> 8)
#if (TARGET!=43)
#error "Not the IAR MSP430 Assembler"
#endif
```

For details of each data definition directive, see Conditional assembly directives, page 56.

**Register symbols**

The following table shows the existing predefined register symbols:

<table>
<thead>
<tr>
<th>Name</th>
<th>Address size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>R4-R15</td>
<td>16 bits</td>
<td>General purpose registers</td>
</tr>
<tr>
<td>PC</td>
<td>16 bits</td>
<td>Program counter</td>
</tr>
<tr>
<td>SP</td>
<td>16 bits</td>
<td>Stack pointer</td>
</tr>
<tr>
<td>SR</td>
<td>16 bits</td>
<td>Status register</td>
</tr>
</tbody>
</table>

*Table 8: Predefined register symbols*

**Programming hints**

This section gives hints on how to write efficient code for the MSP430 IAR Assembler. For information about projects including both assembler and C or Embedded C++ source files, see the MSP430 IAR C/EC++ Compiler Reference Guide.

**ACCESSING SPECIAL FUNCTION REGISTERS**

Specific header files for a number of MSP430 devices are included in the IAR product package, in the `\430\inc` directory. These header files define the device-specific special function registers (SFRs) and interrupt vector numbers.

The header files are intended to be used also with the MSP430 IAR C/EC++ Compiler.

If any assembler-specific additions are needed in the header file, these can be added easily in the assembler-specific part of the file:

```c
ifndef __IAR_SYSTEMS_ASM__
 {assembler-specific defines}
#endif
```
USING C-STYLE PREPROCESSOR DIRECTIVES

The C-style preprocessor directives are processed before other assembler directives. Therefore, do not use preprocessor directives in macros and do not mix them with assembler-style comments.
Assembler options

This chapter first explains how to set the options from the command line, and gives an alphabetical summary of the assembler options. It then provides detailed reference information for each assembler option.

The MSP430 IAR Embedded Workbench™ IDE User Guide describes how to set assembler options in the IAR Embedded Workbench, and gives reference information about the available options.

Setting command line options

To set assembler options from the command line, you include them on the command line, after the `a430` command:

```
a430 [options] [sourcefile] [options]
```

These items must be separated by one or more spaces or tab characters.

If all the optional parameters are omitted the assembler will display a list of available options a screen at a time. Press Enter to display the next screen.

For example, when assembling the source file `power2.s43`, use the following command to generate a list file to the default filename (`power2.lst`):

```
a430 power2 -L
```

Some options accept a filename, included after the option letter with a separating space. For example, to generate a list file with the name `list.lst`:

```
a430 power2 -l list.lst
```

Some other options accept a string that is not a filename. This is included after the option letter, but without a space. For example, to generate a list file to the default filename but in the subdirectory named `list`:

```
a430 power2 -Llist\
```

Note: The subdirectory you specify must already exist. The trailing backslash is required to separate the name of the subdirectory and the default filename.

EXTENDED COMMAND LINE FILE

In addition to accepting options and source filenames from the command line, the assembler can accept them from an extended command line file.
By default, extended command line files have the extension xcl, and can be specified using the \-f\ command line option. For example, to read the command line options from extend.xcl, enter:

\texttt{a430 -f extend.xcl}

### ERROR RETURN CODES

When using the MSP430 IAR Assembler from within a batch file, you may need to determine whether the assembly was successful in order to decide what step to take next. For this reason, the assembler returns the following error return codes:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Assembly successful, warnings may appear</td>
</tr>
<tr>
<td>1</td>
<td>There were warnings (only if the -ws\ option is used)</td>
</tr>
<tr>
<td>2</td>
<td>There were errors</td>
</tr>
</tbody>
</table>

*Table 9: Assembler error return codes*

### ASSEMBLER ENVIRONMENT VARIABLES

Options can also be specified using the \texttt{ASM430} environment variable. The assembler appends the value of this variable to every command line, so it provides a convenient method of specifying options that are required for every assembly.

The following environment variables can be used with the MSP430 IAR Assembler:

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{ASM430}</td>
<td>Specifies command line options; for example: \texttt{set ASM430=-L -ws}</td>
</tr>
<tr>
<td>\texttt{A430_INC}</td>
<td>Specifies directories to search for include files; for example: \texttt{set A430_INC=c:\myinc}</td>
</tr>
</tbody>
</table>

*Table 10: Assembler environment variables*

For example, setting the following environment variable will always generate a list file with the name temp.lst:

\texttt{ASM430=-l temp.lst}

For information about the environment variables used by the IAR XLINK Linker and the IAR XLIB Librarian, see the \textit{IAR Linker and Library Tools Reference Guide}. 
### Summary of assembler options

The following table summarizes the assembler options available from the command line:

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-B</td>
<td>Macro execution information</td>
</tr>
<tr>
<td>-b</td>
<td>Makes a library module</td>
</tr>
<tr>
<td>-c{}</td>
<td>Conditional list</td>
</tr>
<tr>
<td>-Dsymbol[=value]</td>
<td>Defines a symbol</td>
</tr>
<tr>
<td>-E number</td>
<td>Maximum number of errors</td>

*Table 11: Assembler options summary*
**Descriptions of assembler options**

The following sections give full reference information about each assembler option.

- **-B**

  Use this option to make the assembler print macro execution information to the standard output stream on every call of a macro. The information consists of:
  - The name of the macro
  - The definition of the macro
  - The arguments to the macro
  - The expanded text of the macro.

  This option is mainly used in conjunction with the list file options `-L` or `-l`; for additional information, see page 17.

  This option is identical to the `Macro execution info` option on the List page of the A430 category in the IAR Embedded Workbench.

- **-b**

  This option causes the object file to be a library module rather than a program module. By default, the assembler produces a program module ready to be linked with the IAR XLINK Linker. Use the `-b` option if you instead want the assembler to make a library module for use with XLIB.

  If the `NAME` directive is used in the source (to specify the name of the program module), the `-b` option is ignored, i.e. the assembler produces a program module regardless of the `-b` option.

  This option is identical to the `Make a LIBRARY module` option on the Code generation page of the A430 category in the IAR Embedded Workbench.

- **-c**

  Use this option to control the contents of the assembler list file. This option is mainly used in conjunction with the list file options `-L` and `-l`; see page 17 for additional information.
The following table shows the available parameters:

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-cD</td>
<td>Disable list file</td>
</tr>
<tr>
<td>-cM</td>
<td>Macro definitions</td>
</tr>
<tr>
<td>-cE</td>
<td>No macro expansions</td>
</tr>
<tr>
<td>-cA</td>
<td>Assembled lines only</td>
</tr>
<tr>
<td>-cO</td>
<td>Multiline code</td>
</tr>
</tbody>
</table>

This option is related to the List file options on the List page of the A430 category in

```
-D -Dsymbol[-value]
```

Use this option to define a preprocessor symbol with the name symbol and the value value. If no value is specified, 1 is used.

The -D option allows you to specify a value or choice on the command line instead of in the source file.

**Example**

For example, you could arrange your source to produce either the test or production version of your program dependent on whether the symbol TESTVER was defined. To do this, use include sections such as:

```
#ifdef TESTVER
  ...
#endif
```

Then select the version required in the command line as follows:

Production version: `a430 prog`
Test version: `a430 prog -DTESTVER`

Alternatively, your source might use a variable that you need to change often. You can then leave the variable undefined in the source, and use -D to specify the value on the command line; for example:

`a430 prog -DFRAMERATE=3`

This option is related the #define page in the A430 category in the IAR Embedded Workbench.
Descriptions of assembler options

- **E -E number**

  This option specifies the maximum number of errors that the assembler will report.

  By default, the maximum number is 100. The -E option allows you to decrease or increase this number to see more or fewer errors in a single assembly.

- **f -f extend.xcl**

  This option extends the command line with text read from the file named extend.xcl. Notice that there must be a space between the option itself and the filename.

  The -f option is particularly useful where there is a large number of options which are more conveniently placed in a file than on the command line itself.

  **Example**

  To run the assembler with further options taken from the file Extend.xcl, use:

  a430 prog -f extend.xcl

- **G -G**

  This option causes the assembler to read the source from the standard input stream, rather than from a specified source file.

  When -G is used, no source filename may be specified.

- **I -I prefix**

  Use this option to specify paths to be used by the preprocessor by adding the #include file search prefix prefix.

  By default, the assembler searches for #include files only in the current working directory and in the paths specified in the A430_INC environment variable. The -I option allows you to give the assembler the names of directories where it will also search if it fails to find the file in the current working directory.

  **Example**

  Using the options:

  -Ic:\global\ -Ic:\thisproj\headers\  

  and then writing:

  #include "asmlib.h"
in the source, will make the assembler search first in the current directory, then in the
directory \c:\global\, and finally in the directory \c:\thisproj\headers\.

You can also specify the include path with the A430_INC environment variable, see
Assembler environment variables, page 12.

This option is related to the Include page in the A430 category in the IAR Embedded
Workbench.

-i -i

Includes #include files in the list file.

By default, the assembler does not list #include file lines since these often come from
standard files and would waste space in the list file. The -i option allows you to list
these file lines.

This option is identical to the #included text option on the List page of the A430
category in the IAR Embedded Workbench.

-L -L[prefix]

By default the assembler does not generate a list file. Use this option to make the
assembler generate one and send it to file [prefix] sourcename.lst.

To simply generate a listing, use the -L option without a prefix. The listing is sent to the
file with the same name as the source, but the extension will be lst.

The -L option lets you specify a prefix, for example to direct the list file to a
subdirectory. Notice that you cannot include a space before the prefix.

-L may not be used at the same time as -l.

Example

To send the list file to list\prog.lst rather than the default prog.lst:
a430 prog -Llist\

This option is related to the List options in the A430 category in the IAR Embedded
Workbench, as well as to the Output Directories option in the General category

-l -l filename

Use this option to make the assembler generate a listing and send it to the file filename.
If no extension is specified, lst is used. Notice that you must include a space before the
filename.
By default, the assembler does not generate a list file. The -l option generates a listing, and directs it to a specific file. To generate a list file with the default filename, use the -L option instead.

This option is related to the List options in the A430 category in the IAR Embedded Workbench. In the Embedded Workbench the list filename always is sourcefilename.lst.

-M  
This option sets the characters to be used as left and right quotes of each macro argument to a and b respectively.

By default, the characters are < and >. The -M option allows you to change the quote characters to suit an alternative convention or simply to allow a macro argument to contain < or > themselves.

**Example**

For example, using the option:

-M[

in the source you would write, for example:

print [>]

to call a macro print with > as the argument.

This option is identical to the Macro quote chars option on the Code generation page of the A430 category in the IAR Embedded Workbench.

-N  
Use this option to omit the header section that is printed by default in the beginning of the list file.

This option is useful in conjunction with the list file options -L or -l; see page 17 for additional information.

This option is identical to deselecting the option Include header on the List page of the A430 category in the IAR Embedded Workbench.
-o  -0prefix

Use this option to set the prefix to be used on the name of the object file. Notice that you cannot include a space before the prefix.

By default the prefix is null, so the object filename corresponds to the source filename (unless -o is used). The -o option lets you specify a prefix, for example to direct the object file to a subdirectory.

Notice that -0 may not be used at the same time as -o.

**Example**

To send the object code to the file obj\prog.r43 rather than to the default location for prog.r43:

a430 prog -Oobj\

This option is related to the **Output directories** page in the **General** category in the IAR Embedded Workbench.

-0  -o filename

This option sets the filename to be used for the object file. Notice that you must include a space before the filename. If no extension is specified, r43 is used.

The option -0 may not be used at the same time as the option -0.

**Example**

For example, the following command puts the object code to the file obj.r43 instead of the default prog.r43:

a430 prog -o obj

Notice that you must include a space between the option itself and the filename.

This option is related to the filename and directory that you specify when creating a new source file or project in the IAR Embedded Workbench.

-p  -plines

The -p option sets the number of lines per page to lines, which must be in the range 10 to 150.

This option is used in conjunction with the list options -L or -l; see page 17 for additional information.
This option is identical to the **Lines/page** option on the **List** page of the **A430** category in the IAR Embedded Workbench.

- **-r [e|n]**

The **-r** option makes the assembler generate debug information that allows a symbolic debugger such as C-SPY to be used on the program.

By default, the assembler does not generate debug information, to reduce the size and link time of the object file. You must use the **-r** option if you want to use a debugger with the program.

The following table shows the available parameters:

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-re</td>
<td>Includes the full source file into the object file</td>
</tr>
<tr>
<td>-rn</td>
<td>Generates an object file without source information; symbol information will be available.</td>
</tr>
</tbody>
</table>

*Table 13: Generating debug information (-r)*

This option is identical to the **Generate debug information** option on the **Debug** page of the **A430** category in the IAR Embedded Workbench.

- **-s**

The **-s** option causes the assembler to operate without sending any messages to the standard output stream.

By default, the assembler sends various insignificant messages via the standard output stream. Use the **-s** option to prevent this.

The assembler sends error and warning messages to the error output stream, so they are displayed regardless of this setting.

- **-s {+ | -}**

Use the **-s** option to control whether the assembler is sensitive to the case of user symbols:

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-s+</td>
<td>Case sensitive user symbols</td>
</tr>
<tr>
<td>-s-</td>
<td>Case insensitive user symbols</td>
</tr>
</tbody>
</table>

*Table 14: Controlling case sensitivity in user symbols (-s)*
By default, case sensitivity is on. This means that, for example, \texttt{LABEL} and \texttt{label} refer to different symbols. Use \texttt{-s} to turn case sensitivity off, in which case \texttt{LABEL} and \texttt{label} will refer to the same symbol.

This option is identical to the \texttt{Case sensitive user symbols} option on the Code generation page of the \texttt{A430} category in the IAR Embedded Workbench.

\texttt{-t -tn}

By default the assembler sets 8 character positions per tab stop. The \texttt{-t} option allows you to specify a tab spacing to \texttt{n}, which must be in the range 2 to 9.

This option is used in conjunction with the list options \texttt{-L} or \texttt{-l}; see page 17 for additional information.

This option is identical to the \texttt{Tab spacing} option on the List page in the \texttt{A430} category in the IAR Embedded Workbench.

\texttt{-U -Usymbol}

Use the \texttt{-U} option to undefine the predefined symbol \texttt{symbol}.

By default, the assembler provides certain predefined symbols; see \texttt{Predefined symbols}, page 7. The \texttt{-U} option allows you to undefine such a predefined symbol to make its name available for your own use through a subsequent \texttt{-D} option or source definition.

\texttt{Example}

To use the name of the predefined symbol \texttt{__TIME__} for your own purposes, you could undefine it with:

\begin{verbatim}
a430 prog -U __TIME__
\end{verbatim}

This option is identical to the \texttt{#undef} options in the \texttt{A430} category in the IAR Embedded Workbench.

\texttt{-w -w[string][s]}

By default, the assembler displays a warning message when it detects an element of the source which is legal in a syntactical sense, but may contain a programming error; see \texttt{Diagnostics}, page 93, for details.
Use this option to disable warnings. The \texttt{-w} option without a range disables all warnings. The \texttt{-w} option with a range performs the following:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Command line option} & \textbf{Description} \\
\hline
\texttt{-w+} & Enables all warnings. \\
\texttt{-w-} & Disables all warnings. \\
\texttt{-w+n} & Enables just warning \textit{n}. \\
\texttt{-w-n} & Disables just warning \textit{n}. \\
\texttt{-w+m-n} & Enables warnings \textit{m} to \textit{n}. \\
\texttt{-w-m-n} & Disables warnings \textit{m} to \textit{n}. \\
\hline
\end{tabular}
\caption{Disabling assembler warnings (-w)}
\end{table}

Only one \texttt{-w} option may be used on the command line.

By default, the assembler generates exit code 0 for warnings. Use the \texttt{-ws} option to generate exit code 1 if a warning message is produced.

\textbf{Example}

To disable just warning 0 (unreferenced label), use the following command:

\texttt{a430 prog \textasciitilde w-0}

To disable warnings 0 to 8, use the following command:

\texttt{a430 prog \textasciitilde w-0-8}

This option is identical to the Warnings option on the Code generation page of the A430 category in the IAR Embedded Workbench.

\texttt{-x \textasciitilde x\{DI2\}}

Use this option to make the assembler include a cross-reference table at the end of the list file.

This option is used in conjunction with the list options \texttt{-L} or \texttt{-l}; see page 17 for additional information.

The following parameters are available:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Command line option} & \textbf{Description} \\
\hline
\texttt{-xD} & \#defines \\
\texttt{-xI} & Internal symbols \\
\texttt{-x2} & Dual line spacing \\
\hline
\end{tabular}
\caption{Including cross-references in assembler list file (-x)}
\end{table}
This option is identical to the Include cross-reference option on the List page of the A430 category in the IAR Embedded Workbench.
Assembler operators

This chapter first describes the precedence of the assembler operators, and then summarizes the operators, classified according to their precedence. Finally, this chapter provides reference information about each operator, presented in alphabetical order.

Precedence of operators

Each operator has a precedence number assigned to it that determines the order in which the operator and its operands are evaluated. The precedence numbers range from 1 (the highest precedence, i.e. first evaluated) to 7 (the lowest precedence, i.e. last evaluated).

The following rules determine how expressions are evaluated:
- The highest precedence operators are evaluated first, then the second highest precedence operators, and so on until the lowest precedence operators are evaluated.
- Operators of equal precedence are evaluated from left to right in the expression.
- Parentheses ( and ) can be used for grouping operators and operands and for controlling the order in which the expressions are evaluated. For example, the following expression evaluates to 1:

\[ \frac{7}{1+(2*3)} \]

Summary of assembler operators

The following tables give a summary of the operators, in order of priority. Synonyms, where available, are shown after the operator name.

**UNARY OPERATORS – 1**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Unary plus.</td>
</tr>
<tr>
<td>-</td>
<td>Unary minus.</td>
</tr>
<tr>
<td>!, NOT</td>
<td>Logical NOT.</td>
</tr>
<tr>
<td>~, BITNOT</td>
<td>Bitwise NOT.</td>
</tr>
<tr>
<td>LOW</td>
<td>Low byte.</td>
</tr>
<tr>
<td>HIGH</td>
<td>High byte.</td>
</tr>
<tr>
<td>LWRD</td>
<td>Low word.</td>
</tr>
</tbody>
</table>
Summary of assembler operators

**MULTIPLICATIVE ARITHMETIC OPERATORS – 2**
- `*` Multiplication.
- `/` Division.
- `%`, `MOD` Modulo.

**ADDITIVE ARITHMETIC OPERATORS – 3**
- `+` Addition.
- `-` Subtraction.

**SHIFT OPERATORS – 4**
- `>>, SHR` Logical shift right.
- `<`, `SHL` Logical shift left.

**AND OPERATORS – 5**
- `&&`, `AND` Logical AND.
- `&`, `BITAND` Bitwise AND.

**OR OPERATORS – 6**
- `||`, `OR` Logical OR.
- `XOR` Logical exclusive OR.
- `|`, `BITOR` Bitwise OR.
- `^`, `BITXOR` Bitwise exclusive OR.

**OTHER OPERATORS**
- `HWRD` High word.
- `DATE` Current time/date.
- `SFB` Segment begin.
- `SFE` Segment end.
- `SIZEOF` Segment size.
**COMPARISON OPERATORS – 7**

- `-`, `==`, `EQ` Equal.
- `<>`, `!=`, `NE` Not equal.
- `>`, `GT` Greater than.
- `<`, `LT` Less than.
- `UGT` Unsigned greater than.
- `ULT` Unsigned less than.
- `>=`, `GE` Greater than or equal.
- `<=`, `LE` Less than or equal.

### Description of operators

The following sections give detailed descriptions of each assembler operator. The number within parentheses specify the priority of the operator. See *Assembler expressions*, page 4, for related information.

* Multiplication (2).
  * produces the product of its two operands. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

**Example**

\[
2 \times 2 \rightarrow 4 \\
-2 \times 2 \rightarrow -4
\]

+ Unary plus (1).
  Unary plus operator.

**Example**

\[
+3 \rightarrow 3 \\
3 + 2 \rightarrow 6
\]

* Addition (3).
  The + addition operator produces the sum of the two operands which surround it. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.
Description of operators

\[ \begin{align*}
\text{Example} \\
92 + 19 & \rightarrow 111 \\
-2 + 2 & \rightarrow 0 \\
-2 + -2 & \rightarrow -4 \\
\end{align*} \]

- Unary minus (1).

The unary minus operator performs arithmetic negation on its operand.

The operand is interpreted as a 32-bit signed integer and the result of the operator is the two’s complement negation of that integer.

\[ \begin{align*}
\text{Example} \\
-3 & \rightarrow -3 \\
3 \times -2 & \rightarrow -6 \\
4 - -5 & \rightarrow 9 \\
\end{align*} \]

- Subtraction (3).

The subtraction operator produces the difference when the right operand is taken away from the left operand. The operands are taken as signed 32-bit integers and the result is also signed 32-bit integer.

\[ \begin{align*}
\text{Example} \\
92 - 19 & \rightarrow 73 \\
-2 - 2 & \rightarrow -4 \\
-2 - -2 & \rightarrow 0 \\
\end{align*} \]

/ Division (2).

/ produces the integer quotient of the left operand divided by the right operator. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

\[ \begin{align*}
\text{Example} \\
9 / 2 & \rightarrow 4 \\
-12 / 3 & \rightarrow -4 \\
9 / 2 \times 6 & \rightarrow 24 \\
\end{align*} \]
\textbf{\textless \textgreater} \text{ Less than (7).}

If the left operand has a lower numeric value than the right operand, then the result will be 1 (true), otherwise 0 (false).

\textbf{Example}
\begin{verbatim}
-1 < 2 \rightarrow 1
2 < 1 \rightarrow 0
2 < 2 \rightarrow 0
\end{verbatim}

\textbf{\textless= \textgreater= \textless\textgreater, \textgreater\textless \text{ Less than or equal (7)\textless\textgreater \textless\textgreater}}

\textless= \text{evaluates to 1 (true) if the left operand has a lower or equal numeric value to the right operand, otherwise 0 (false).}

\textbf{Example}
\begin{verbatim}
1 <= 2 \rightarrow 1
2 <= 1 \rightarrow 0
1 <= 1 \rightarrow 1
\end{verbatim}

\textbf{\textless\textgreater, \textgreater\textless \textless\textgreater, \textgreater\textless \text{ Not equal (7).}}

\textless\textgreater \text{evaluates to 0 (false) if its two operands are identical in value or to 1 (true) if its two operands are not identical in value.}

\textbf{Example}
\begin{verbatim}
1 <> 2 \rightarrow 1
2 <> 2 \rightarrow 0
'A' <> 'B' \rightarrow 1
\end{verbatim}

\textbf{\textless\textgreater\textless \textgreater\textless \textless\textgreater\textless \textgreater\textless \text{ Equal (7).}}

\textless\textgreater \text{evaluates to 1 (true) if its two operands are identical in value, or to 0 (false) if its two operands are not identical in value.}

\textbf{Example}
\begin{verbatim}
1 = 2 \rightarrow 0
2 == 2 \rightarrow 1
'ABC' = 'ABCD' \rightarrow 0
\end{verbatim}
Description of operators

> Greater than (7).
> evaluates to 1 (true) if the left operand has a higher numeric value than the right operand, otherwise 0 (false).

   Example
   \[-1 > 1 \rightarrow 0\]
   \[2 > 1 \rightarrow 1\]
   \[1 > 1 \rightarrow 0\]

>= Greater than or equal (7).
>= evaluates to 1 (true) if the left operand is equal to or has a higher numeric value than the right operand, otherwise 0 (false).

   Example
   \[1 \geq 2 \rightarrow 0\]
   \[2 \geq 1 \rightarrow 1\]
   \[1 \geq 1 \rightarrow 1\]

&& Logical AND (5).
Use && to perform logical AND between its two integer operands. If both operands are non-zero the result is 1 (true); otherwise it is 0 (zero).

   Example
   \[\text{B'}1010 \& \text{B'}0011 \rightarrow 1\]
   \[\text{B'}1010 \& \text{B'}0101 \rightarrow 1\]
   \[\text{B'}1010 \& \text{B'}0000 \rightarrow 0\]

& Bitwise AND (5).
Use & to perform bitwise AND between the integer operands.

   Example
   \[\text{B'}1010 \& \text{B'}0011 \rightarrow \text{B'}0010\]
   \[\text{B'}1010 \& \text{B'}0101 \rightarrow \text{B'}0000\]
   \[\text{B'}1010 \& \text{B'}0000 \rightarrow \text{B'}0000\]
Assembler operators

~ Bitwise NOT (1).
Use ~ to perform bitwise NOT on its operand. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

**Example**

\[
\sim B'1010 \rightarrow B'11111111111111111111111111110101
\]

| Bitwise OR (6).
Use | to perform bitwise OR on its operands.

**Example**

\[
B'1010 | B'0101 \rightarrow B'1111 \quad B'1010 | B'0000 \rightarrow B'1010
\]

^ Bitwise exclusive OR (6).
Use ^ to perform bitwise XOR on its operands.

**Example**

\[
B'1010 ^ B'0101 \rightarrow B'1111 \quad B'1010 ^ B'0011 \rightarrow B'1001
\]

% Modulo (2).
% produces the remainder from the integer division of the left operand by the right operand. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

\[
X \% Y \text{ is equivalent to } X - Y \ast (X/Y) \text{ using integer division.}
\]

**Example**

\[
2 \% 2 \rightarrow 0 \\
12 \% 7 \rightarrow 5 \\
3 \% 2 \rightarrow 1
\]
Logical NOT (1).

Use ! to negate a logical argument.

**Example**

\[ \begin{align*}
! B'0101 & \rightarrow 0 \\
! B'0000 & \rightarrow 1
\end{align*} \]

Logical OR (6).

Use | | to perform a logical OR between two integer operands.

**Example**

\[ \begin{align*}
B'1010 | | B'0000 & \rightarrow 1 \\
B'0000 | | B'0000 & \rightarrow 0
\end{align*} \]

**DATE**

Current time/date (1).

Use the DATE operator to specify when the current assembly began.

The DATE operator takes an absolute argument (expression) and returns:

- **DATE 1**: Current second (0–59).
- **DATE 2**: Current minute (0–59).
- **DATE 3**: Current hour (0–23).
- **DATE 4**: Current day (1–31).
- **DATE 5**: Current month (1–12).
- **DATE 6**: Current year MOD 100 (1998 → 98, 2000 → 00, 2002 → 02).

**Example**

To assemble the date of assembly:

`today: DC8 DATE 5, DATE 4, DATE 3`
**Assembler operators**

**HIGH**

HIGH byte (1).

HIGH takes a single operand to its right which is interpreted as an unsigned, 16-bit integer value. The result is the unsigned 8-bit integer value of the higher order byte of the operand.

*Example*

\[
\text{HIGH } 0xABCD \rightarrow 0xAB
\]

**HWRD**

High word (1).

HWRD takes a single operand, which is interpreted as an unsigned, 32-bit integer value. The result is the high word (bits 31 to 16) of the operand.

*Example*

\[
\text{HWRD } 0x12345678 \rightarrow 0x1234
\]

**LOW**

Low byte (1).

LOW takes a single operand, which is interpreted as an unsigned, 32-bit integer value. The result is the unsigned, 8-bit integer value of the lower order byte of the operand.

*Example*

\[
\text{LOW } 0xABCD \rightarrow 0xCD
\]

**LWRD**

Low word (1).

LWRD takes a single operand, which is interpreted as an unsigned, 32-bit integer value. The result is the low word (bits 15 to 0) of the operand.

*Example*

\[
\text{LWRD } 0x12345678 \rightarrow 0x5678
\]

**SFB**

Segment begin (1).

*Syntax*

\[
\text{SFB\{segment [\{+\|-\}offset]\}}
\]
Description of operators

Parameters

\textit{SFB} accepts a single operand to its right. The operand must be the name of a relocatable segment. The operator evaluates to the absolute address of the first byte of that segment. This evaluation takes place at linking time.

Example

\begin{verbatim}
NAME demo
RSEG CODE
start: DC16 SFB(CODE)
\end{verbatim}

Even if the above code is linked with many other modules, \texttt{start} will still be set to the address of the first byte of the segment.

\textbf{SFE} Segment end (1).

Syntax

\begin{verbatim}
SFE (segment [{+ | -} offset])
\end{verbatim}

Parameters

\begin{itemize}
  \item \textit{segment} The name of a relocatable segment, which must be defined before \texttt{SFE} is used.
  \item \textit{offset} An optional offset from the start address. The parentheses are optional if \texttt{offset} is omitted.
\end{itemize}

Description

\texttt{SFE} accepts a single operand to its right. The operand must be the name of a relocatable segment. The operator evaluates to the segment start address plus the segment size. This evaluation takes place at linking time.
Even if the above code is linked with many other modules, end will still be set to the address of the last byte of the segment.

The size of the segment MY_SEGMENT can be calculated as:

```
SFE(MY_SEGMENT) - SFH(MY_SEGMENT)
```

### Logical shift left (4)

Use `<<` to shift the left operand, which is always treated as `unsigned`, to the left. The number of bits to shift is specified by the right operand, interpreted as an integer value between 0 and 32.

**Example**

```
B'00011100 << 3  \rightarrow  B'11100000
B'0000011111111111 << 5  \rightarrow  B'1111111111111111000000
14 << 1  \rightarrow  28
```

### Logical shift right (4)

Use `>>` to shift the left operand, which is always treated as `unsigned`, to the right. The number of bits to shift is specified by the right operand, interpreted as an integer value between 0 and 32.

**Example**

```
B'01110000 >> 3  \rightarrow  B'00001110
B'1111111111111111 >> 20  \rightarrow  0
14 >> 1  \rightarrow  7
```

### SIZEOF

Segment size (1).

**Syntax**

```
SIZEOF segment
```
### Description of operators

**Parameters**

*segment*  
The name of a relocatable segment, which must be defined before SIZEOF is used.

**Description**

SIZEOF generates *SPE-SFP* for its argument, which should be the name of a relocatable segment; i.e. it calculates the size in bytes of a segment. This is done when modules are linked together.

**Example**

```
NAME demo
RSEG CODE
size: DC16 SIZEOF CODE
```

sets size to the size of segment CODE.

---

**UGT**  
Unsigned greater than (7).

UGT evaluates to 1 (true) if the left operand has a larger value than the right operand, otherwise 0 (false). The operation treats its operands as unsigned values.

**Example**

```
2 UGT 1  →  1
-1 UGT 1  →  0
```

---

**ULT**  
Unsigned less than (7).

ULT evaluates to 1 (true) if the left operand has a smaller value than the right operand, otherwise 0 (false). The operation treats its operands as unsigned values.

**Example**

```
1 ULT 2  →  1
-1 ULT 2  →  0
```
XOR

Logical exclusive OR (6).

Use XOR to perform logical XOR on its two operands.

**Example**

\[
\begin{align*}
\text{B'0101 XOR B'1010} & \rightarrow 0 \\
\text{B'0101 XOR B'0000} & \rightarrow 1
\end{align*}
\]
Description of operators
Assembler directives

This chapter gives an alphabetical summary of the assembler directives. It then describes the syntax conventions and provides detailed reference information for each category of directives.

Summary of assembler directives

The following table gives a summary of all the assembler directives.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
<th>Section</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>.</code></td>
<td>Includes a file.</td>
<td>Assembler control</td>
</tr>
<tr>
<td><code>#define</code></td>
<td>Assigns a value to a label.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#elif</code></td>
<td>Introduces a new condition in a <code>#if...#endif</code></td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#else</code></td>
<td>Assembles instructions if a condition is false.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#endif</code></td>
<td>Ends a <code>#if</code>, <code>#ifdef</code>, or <code>#ifndef</code> block.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#error</code></td>
<td>Generates an error.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#if</code></td>
<td>Assembles instructions if a condition is true.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#ifdef</code></td>
<td>Assembles instructions if a symbol is defined.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#ifndef</code></td>
<td>Assembles instructions if a symbol is undefined.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#include</code></td>
<td>Includes a file.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#message</code></td>
<td>Generates a message on standard output.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>#undef</code></td>
<td>Undefines a label.</td>
<td>C-style preprocessor</td>
</tr>
<tr>
<td><code>/*comment*/</code></td>
<td>C-style comment delimiter.</td>
<td>Assembler control</td>
</tr>
<tr>
<td><code>//</code></td>
<td>C++ style comment delimiter.</td>
<td>Assembler control</td>
</tr>
<tr>
<td><code>=</code></td>
<td>Assigns a permanent value local to a module.</td>
<td>Value assignment</td>
</tr>
<tr>
<td><code>ALIAS</code></td>
<td>Assigns a permanent value local to a module.</td>
<td>Value assignment</td>
</tr>
<tr>
<td><code>ALIGN</code></td>
<td>Aligns the location counter by inserting zero-filled bytes.</td>
<td>Segment control</td>
</tr>
<tr>
<td><code>ALIGNRAM</code></td>
<td>Aligns the program location counter.</td>
<td>Segment control</td>
</tr>
<tr>
<td><code>ASEG</code></td>
<td>Begins an absolute segment.</td>
<td>Segment control</td>
</tr>
<tr>
<td><code>ASEGN</code></td>
<td>Begins a named absolute segment.</td>
<td>Segment control</td>
</tr>
<tr>
<td><code>ASSIGN</code></td>
<td>Assigns a temporary value.</td>
<td>Value assignment</td>

Table 17: Assembler directives summary (Continued)
Note: The IAR Systems toolkit for the MSP430 microcontroller also supports the static overlay directives \texttt{FUNCALL}, \texttt{FUNCTION}, \texttt{LOCFRAME}, and \texttt{ARGFRAME} that are designed to ease coexistence of routines written in C and assembler language. (Static overlay is not, however, relevant for this product.)

### Module control directives

Module control directives are used for marking the beginning and end of source program modules, and for assigning names and types to them.

<table>

Table 18: Module control directives
Directive | Description
--- | ---
LIBRARY | Begins a library module.
MODULE | Begins a library module.
NAME | Begins a program module.
PROGRAM | Begins a program module
RTMODEL | Declares runtime model attributes.

Table 18: Module control directives (Continued)

**SYNTAX**

END [label]
ENDMOD [label]
LIBRARY symbol [(expr)]
MODULE symbol [(expr)]
NAME symbol [(expr)]
PROGRAM symbol [(expr)]
RTMODEL key, value

**PARAMETERS**

expr | Optional expression (0–255) used by the IAR compiler to encode programming language, memory model, and processor configuration.
key | A text string specifying the key.
label | An expression or label that can be resolved at assembly time. It is output in the object code as a program entry address.
symbol | Name assigned to module, used by XLINK, XAR, and XLIB when processing object files.
value | A text string specifying the value.

**DESCRIPTION**

**Beginning a program module**

Use NAME, alternatively PROGRAM, to begin a program module, and to assign a name for future reference by the IAR XLINK Linker™, the IAR XAR Library Builder™, and the IAR XLIB Librarian™.

Program modules are unconditionally linked by XLINK, even if other modules do not reference them.
Module control directives

Beginning a library module

Use `MODULE`, alternatively `LIBRARY`, to create libraries containing a number of small modules—like runtime systems for high-level languages—where each module often represents a single routine. With the multi-module facility, you can significantly reduce the number of source and object files needed.

Library modules are only copied into the linked code if other modules reference a public symbol in the module.

Terminating a module

Use `ENDMOD` to define the end of a module.

Terminating the last module

Use `END` to indicate the end of the source file. Any lines after the `END` directive are ignored.

Assembling multi-module files

Program entries must be either relocatable or absolute, and will show up in the XLINK list file, as well as in some of the hexadecimal absolute output formats. Program entries must not be defined externally.

The following rules apply when assembling multi-module files:

- At the beginning of a new module all user symbols are deleted, except for those created by `DEFINE`, `#define`, or `MACRO`, the location counters are cleared, and the mode is set to absolute.
- Listing control directives remain in effect throughout the assembly.

Note: `END` must always be used in the last module, and there must not be any source lines (except for comments and listing control directives) between an `ENDMOD` and a `MODULE` directive.

If the `NAME` or `MODULE` directive is missing, the module will be assigned the name of the source file and the attribute `program`.

Declaring runtime model attributes

Use `RTMODEL` to enforce consistency between modules. All modules that are linked together and define the same runtime attribute key must have the same value for the corresponding key value, or the special value `*`. Using the special value `*` is equivalent to not defining the attribute at all. It can however be useful to explicitly state that the module can handle any runtime model.

A module can have several runtime model definitions.
Note: The compiler runtime model attributes start with double underscore. In order to avoid confusion, this style must not be used in the user-defined assembler attributes.

If you are writing assembler routines for use with C code, and you want to control the module consistency, refer to the MSP430 IAR C/EC++ Compiler Reference Guide.

Examples

The following example defines three modules where:

- MOD_1 and MOD_2 cannot be linked together since they have different values for runtime model "foo".
- MOD_1 and MOD_3 can be linked together since they have the same definition of runtime model "bar" and no conflict in the definition of "foo".
- MOD_2 and MOD_3 can be linked together since they have no runtime model conflicts. The value "*" matches any runtime model value.

```asm
MODULE MOD_1
  RTMODEL   "foo", "1"
  RTMODEL   "bar", "XXX"
  ...
ENDMOD

MODULE MOD_2
  RTMODEL   "foo", "2"
  RTMODEL   "bar", "**"
  ...
ENDMOD

MODULE MOD_3
  RTMODEL   "bar", "XXX"
  ...
END
```

Symbol control directives

These directives control how symbols are shared between modules.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERN (IMPORT)</td>
<td>Imports an external symbol.</td>
</tr>
<tr>
<td>PUBLIC (EXPORT)</td>
<td>Exports symbols to other modules.</td>
</tr>
<tr>
<td>PUBWEAK</td>
<td>Exports symbols to other modules, multiple definitions allowed.</td>
</tr>
<tr>
<td>REQUIRE</td>
<td>Forces a symbol to be referenced.</td>
</tr>
</tbody>
</table>

Table 19: Symbol control directives
Symbol control directives

SYNTAX
EXTERN symbol [,...,symbol] ...
PUBLIC symbol [,...,symbol] ...
PUBWEAK symbol [,...,symbol] ...
REQUIRE symbol

PARAMETERS
symbol Symbol to be imported or exported.

DESCRIPTION
Exporting symbols to other modules
Use PUBLIC to make one or more symbols available to other modules. Symbols declared PUBLIC can be relocatable or absolute, and can also be used in expressions (with the same rules as for other symbols).

The PUBLIC directive always exports full 32-bit values, which makes it feasible to use global 32-bit constants also in assemblers for 8-bit and 16-bit processors. With the LOW, HIGH, >>, and << operators, any part of such a constant can be loaded in an 8-bit or 16-bit register or word.

There are no restrictions on the number of PUBLIC-declared symbols in a module.

Exporting symbols with multiple definitions to other modules
PUBWEAK is similar to PUBLIC except that it allows the same symbol to be defined several times. Only one of those definitions will be used by XLINK. If a module containing a PUBLIC definition of a symbol is linked with one or more modules containing PUBWEAK definitions of the same symbol, XLINK will use the PUBLIC definition. If there are more than one PUBWEAK definitions, XLINK will use the first definition.

A symbol defined as PUBWEAK must be a label in a segment part, and it must be the only symbol defined as PUBLIC or PUBWEAK in that segment part.

Note: Library modules are only linked if a reference to a symbol in that module is made, and that symbol has not already been linked. During the module selection phase, no distinction is made between PUBLIC and PUBWEAK definitions. This means that to ensure that the module containing the PUBLIC definition is selected, you should link it before the other modules, or make sure that a reference is made to some other PUBLIC symbol in that module.
Importing symbols

Use EXTERN to import an untyped external symbol.

The REQUIRE directive marks a symbol as referenced. This is useful if the segment part containing the symbol must be loaded even if the code is not referenced.

EXAMPLES

The following example defines a subroutine to print an error message, and exports the entry address err so that it can be called from other modules. It defines print as an external routine; the address will be resolved at link time.

```
NAME error
EXTERN print
PUBLIC err

err CALL print
DB "*** Error ***"
EVEN
RET
END
```
SYNTAX
ALIGN align [,value]
ALIGNRAM align
ASEG [start [((align)]]
ASEGN segment [:type], address
COMMON segment [:type] [(align)]
EVEN [value]
ORG expr
RSEG segment [:type] [flag] [(align)]
RSEG segment [:type], address
STACK segment [:type] [(align)]

PARAMETERS
address Address where this segment part will be placed.
align Exponent of the value to which the address should be aligned, in the range 0 to 30.
expr Address to set the location counter to.
flag NORoot
This segment part is discarded by the linker if no symbols in this segment part are referred to. Normally all segment parts except startup code and interrupt vectors should set this flag. The default mode is ROOT which indicates that the segment part must not be discarded.
REORDER
Allows the linker to reorder segment parts. For a given segment, all segment parts must specify the same state for this flag. The default mode is NOREORDER which indicates that the segment parts must remain in order.
SORT
The linker will sort the segment parts in decreasing alignment order. For a given segment, all segment parts must specify the same state for this flag. The default mode is NOSORT which indicates that the segment parts will not be sorted.
segment The name of the segment.
start A start address that has the same effect as using an ORG directive at the beginning of the absolute segment.
type The memory type, typically CODE, or DATA. In addition, any of the types supported by the IAR XLINK Linker.
value Value used for padding byte(s), default is zero.
DESCRIPTION

Use the align parameter in any of these directives to align the segment start address.

Beginning an absolute segment

Use ASEG to set the absolute mode of assembly, which is the default at the beginning of a module.

If the parameter is omitted, the start address of the first segment is 0, and subsequent segments continue after the last address of the previous segment.

Note: If a move of an immediate value to an absolute address, for example

MOV #0x1234, 0x300

is made in a relocatable or absolute segment, the offset is calculated as if the code begun at address 0x0000. The assembler does not take into account the placement of the segment.

Beginning a named absolute segment

Use ASEGN to start a named absolute segment located at the address address.

This directive has the advantage of allowing you to specify the memory type of the segment.

Beginning a relocatable segment

Use RSEG to set the current mode of the assembly to relocatable assembly mode. The assembler maintains separate location counters (initially set to zero) for all segments, which makes it possible to switch segments and mode anytime without the need to save the current segment location counter.

Up to 65536 unique, relocatable segments may be defined in a single module.

Beginning a stack segment

Use STACK to allocate code or data allocated from high to low addresses (in contrast with the RSEG directive that causes low-to-high allocation).

Note: The contents of the segment are not generated in reverse order.

Beginning a common segment

Use COMMON to place data in memory at the same location as COMMON segments from other modules that have the same name. In other words, all COMMON segments of the same name will start at the same location in memory and overlay each other.
Obviously, the COMMON segment type should not be used for overlaid executable code. A typical application would be when you want a number of different routines to share a reusable, common area of memory for data.

It can be practical to have the interrupt vector table in a COMMON segment, thereby allowing access from several routines.

The final size of the COMMON segment is determined by the size of largest occurrence of this segment. The location in memory is determined by the XLINK -Z command; see the IAR Linker and Library Tools Reference Guide.

**Setting the program location counter (PLC)**

Use ORG to set the program location counter of the current segment to the value of an expression. The optional label will assume the value and type of the new location counter.

The result of the expression must be of the same type as the current segment, i.e. it is not valid to use ORG 10 during RSEG, since the expression is absolute; use ORG $+10 instead. The expression must not contain any forward or external references.

All program location counters are set to zero at the beginning of an assembly module.

**Aligning a segment**

Use the directive ALIGN to align the program location counter to a specified address boundary. The parameter align is used in any expression which gives the power of two to which the program counter should be aligned and the permitted range is 0 to 8.

The alignment is made relative to the segment start; normally this means that the segment alignment must be at least as large as that of the alignment directive to give the desired result.

ALIGN aligns by inserting zero/filled bytes, up to a maximum of 255. The EVEN directive aligns the program counter to an even address (which is equivalent to ALIGN 1) and the ODD directive aligns the program location counter to an odd address. The value used for padding bytes must be within the range 0 to 255.

Use ALIGNRAM to align the program location counter by incrementing it; no data is generated. The parameter align can be within the range 0 to 31.

**EXAMPLES**

**Beginning an absolute segment**

The following example assembles the jump to the function main in address 0. On RESET, the chip sets PC to address 0.
NAME reset
EXTERN main

ASEG
ORG 0xFFFE ; RESET vector address
reset: DC16 main ; Instruction that ; executes on startup
end

Beginning a relocatable segment
The following directive aligns the start address of segment MYSEG (upwards) to the nearest 8 byte ($2^{3}$) page boundary:
RSEG MYSEG:CODE(3)
Note that only the first segment directive for a particular segment can contain an alignment operand.

Beginning a stack segment
The following example defines two 100-byte stacks in a relocatable segment called rpnstack:
STACK rpnstack
parms DS8 100
opers DS8 100
END
The data is allocated from high to low addresses.

Beginning a common segment
The following example defines two common segments containing variables:
NAME common1
COMMON data
count DS8 4
ENMOD
NAME common2
COMMON data
up DS8 1
ORG $+2
down DS8 1
END
Because the common segments have the same name, `data`, the variables up and down refer to the same locations in memory as the first and last bytes of the 4-byte variable `count`.

### Setting the location counter

The following example uses `ORG` to leave a gap of 256 bytes:

```assembly
NAME org
ORG $+256
begin MOV #12,R4
SUB R5,R4
RET
END begin
```

### Aligning a segment

This example starts a relocatable segment, moves to an even address, and adds some data. It then aligns to a 64-byte boundary before creating a 64-byte table.

```assembly
RSEG data ; Start a relocatable data segment
EVEN ; Ensure it’s on an even boundary
target DC16 1 ; target and best will be on
; an even boundary
best DC16 1
ALIGN 6 ; Now align to a 64 byte boundary
results DS8 64 ; And create a 64 byte table
END
```

---

**Value assignment directives**

These directives are used for assigning values to symbols.

<table>
<thead>

</table>

*Table 21: Value assignment directives*
Assembler directives

SYNTAX

label = expr
label ALIAS expr
label ASSIGN expr
label DEFINE expr
label EQU expr
LIMIT expr, min, max, message
[const] SFRTYPE register = value
[const] SFRTYPE register attribute [,attribute] = value
[const] SFRW register = value
label VAR expr

PARAMETERS

attribute One or more of the following:
  BYTE  The SFR must be accessed as a byte.
  READ  You can read from this SFR.
  WORD  The SFR must be accessed as a word.
  WRITE You can write to this SFR.

expr  Value assigned to symbol or value to be tested.
label  Symbol to be defined.
message A text message that will be printed when expr is out of range.
min, max The minimum and maximum values allowed for expr.
register The special function register.
value  The SFR port address.

DESCRIPTION

Defining a temporary value

Use either of ASSIGN and VAR to define a symbol that may be redefined, such as for use with macro variables. Symbols defined with VAR cannot be declared PUBLIC.
**Defining a permanent local value**

Use `EQU` or `=` to assign a value to a symbol.

Use `EQU` to create a local symbol that denotes a number or offset.

The symbol is only valid in the module in which it was defined, but can be made available to other modules with a `PUBLIC` directive.

Use `EXTERN` to import symbols from other modules.

**Defining a permanent global value**

Use `DEFINE` to define symbols that should be known to all modules in the source file.

A symbol which has been given a value with `DEFINE` can be made available to modules in other files with the `PUBLIC` directive.

Symbols defined with `DEFINE` cannot be redefined within the same file.

**Defining special function registers**

Use `SFRB` to create special function register labels with attributes `READ`, `WRITE`, and `BYTE` turned on. Use `SFRW` to create special function register labels with attributes `READ`, `WRITE`, or `WORD` turned on. Use `SFRTYPE` to create special function register labels with specified attributes.

Prefix the directive with `const` to disable the `WRITE` attribute assigned to the SFR. You will then get an error or warning message when trying to write to the SFR. The `const` keyword must be placed on the same line as the directive.

**Checking symbol values**

Use `LIMIT` to check that expressions lie within a specified range. If the expression is assigned a value outside the range, an error message will appear.

The check will occur as soon as the expression is resolved, which will be during linking if the expression contains external references. The `min` and `max` expressions cannot involve references to forward or external labels, i.e. they must be resolved when encountered.
EXAMPLES

Redefining a symbol

The following example uses SET to redefine the symbol cons in a REPT loop to generate a table of the first 8 powers of 3:

```assembly
NAME table
main ; Generate a table of powers of 3
cons SET 1
REPT
   DC16 cons
ENDR
END main
```

Using local and global symbols

In the following example the symbol value defined in module add1 is local to that module; a distinct symbol of the same name is defined in module add2. The DEFINE directive is used for declaring locn for use anywhere in the file:

```assembly
NAME add1
locn DEFINE 100h
value EQU 77
MOV locn,R4
ADD #value,R4
ENDMOD

NAME add2
value EQU 88
MOV locn,R5
ADD #value,R5
END
```

The symbol locn defined in module add1 is also available to module add2.

Using special function registers

In this example a number of SFR variables are declared with a variety of access capabilities:

```assembly
SFRB portd = 0x212 /* byte read/write access */
SFRW ocr1 = 0x22A /* word read/write access */
const SFRB pind = 0x210 /* byte read only access */
SFRTYPE portb write, byte = 0x218 /* byte write only access */
```
Using the LIMIT directive

The following example sets the value of a variable called speed and then checks it, at assembly time, to see if it is in the range 10 to 30. This might be useful if speed is often changed at compile time, but values outside a defined range would cause undesirable behavior.

```
speed     VAR        23
LIMIT     speed,10,30,“speed out of range”
```

Conditional assembly directives

These directives provide logical control over the selective assembly of source code.

<table>
<thead>
<tr>

<tr>
<td>ELSEIF</td>
<td>Specifies a new condition in an IF...ENDIF block.</td>
</tr>
<tr>
<td>ENDIF</td>
<td>Ends an IF block.</td>
</tr>
</tbody>
</table>

Table 22: Conditional assembly directives

SYNTAX

```
IF condition
ELSE
ELSEIF condition
ENDIF
```

PARAMETERS

condition

One of the following:

- An absolute expression
  - The expression must not contain forward or external references, and any non-zero value is considered as true.
  - `string1=string2`
    - The condition is true if `string1` and `string2` have the same length and contents.
  - `string1<>string2`
    - The condition is true if `string1` and `string2` have different length or contents.
DESCRIPTION

Use the IF, ELSE, and ENDIF directives to control the assembly process at assembly time. If the condition following the IF directive is not true, the subsequent instructions will not generate any code (i.e. it will not be assembled or syntax checked) until an ELSE or ENDIF directive is found.

Use ELSEIF to introduce a new condition after an IF directive. Conditional assembler directives may be used anywhere in an assembly, but have their greatest use in conjunction with macro processing.

All assembler directives (except END) as well as the inclusion of files may be disabled by the conditional directives. Each IF directive must be terminated by an ENDIF directive. The ELSE directive is optional, and if used, it must be inside an IF...ENDIF block. IF...ENDIF and IF...ELSE...ENDIF blocks may be nested to any level.

EXAMPLES

The following macro assembles instructions to increment R4 by a constant, but omits them if the argument is 0:

```
NAME addi
addi MACRO k
    IF k <> 0
        ADD #k,R4
    ENDIF
ENDM
```

It could be tested with the following program:

```
main MOV #23,R4
    addi 7
END main
```

Macro processing directives

These directives allow user macros to be defined.

<table>

</tr>
</tbody>
</table>

| Table 23: Macro processing directives (Continued) |

**PARAMETERS**

- **actual**: String to be substituted.
- **argument**: A symbolic argument name.
- **expr**: An expression.
- **formal**: Argument into which each character of `actual` (REPTC) or each `actual` (REPTI) is substituted.
- **name**: The name of the macro.
- **symbol**: Symbol to be local to the macro.

**DESCRIPTION**

A macro is a user-defined symbol that represents a block of one or more assembler source lines. Once you have defined a macro you can use it in your program like an assembler directive or assembler mnemonic.

When the assembler encounters a macro, it looks up the macro's definition, and inserts the lines that the macro represents as if they were included in the source file at that position.

Macros perform simple text substitution effectively, and you can control what they substitute by supplying parameters to them.
Defining a macro

You define a macro with the statement:

```
macroname MACRO [,arg] [,arg] …
```

Here `macroname` is the name you are going to use for the macro, and `arg` is an argument for values that you want to pass to the macro when it is expanded.

For example, you could define a macro `ERROR` as follows:

```
errmac MACRO text
    CALL abort
    DC8 text,0
    EVEN
ENDM
```

This macro uses a parameter `text` to set up an error message for a routine `abort`. You would call the macro with a statement such as:

```
errmac 'Disk not ready'
```

The assembler will expand this to:

```
    CALL abort
    DC8 'Disk not ready',0
    EVEN
```

If you omit a list of one or more arguments, the arguments you supply when calling the macro are called \1 to \9 and \A to \Z.

The previous example could therefore be written as follows:

```
errmac MACRO
    CALL abort
    DC8 \1,0
    EVEN
ENDM
```

Use the `EXITM` directive to generate a premature exit from a macro.

`EXITM` is not allowed inside `REPT...ENDR`, `REPTC...ENDR`, or `REPTI...ENDR` blocks.

Use `LOCAL` to create symbols local to a macro. The `LOCAL` directive must be used before the symbol is used.

Each time that a macro is expanded, new instances of local symbols are created by the `LOCAL` directive. Therefore, it is legal to use local symbols in recursive macros.

**Note:** It is illegal to redefine a macro.
Passing special characters

Macro arguments that include commas or white space can be forced to be interpreted as one argument by using the matching quote characters < and > in the macro call.

For example:

```
macld MACRO      regs
          ADD     regs
          ENDM
```

The macro can be called using the macro quote characters:

```
macld <R4,RS>
END
```

You can redefine the macro quote characters with the `-M` command line option; see `-M`, page 18.

How macros are processed

There are three distinct phases in the macro process:

1. The assembler performs scanning and saving of macro definitions. The text between `MACRO` and `ENDM` is saved but not syntax checked. Include-file references `$file` are recorded and will be included during macro expansion.

2. A macro call forces the assembler to invoke the macro processor (expander). The macro expander switches (if not already in a macro) the assembler input stream from a source file to the output from the macro expander. The macro expander takes its input from the requested macro definition.

   The macro expander has no knowledge of assembler symbols since it only deals with text substitutions at source level. Before a line from the called macro definition is handed over to the assembler, the expander scans the line for all occurrences of symbolic macro arguments, and replaces them with their expansion arguments.

3. The expanded line is then processed as any other assembler source line. The input stream to the assembler will continue to be the output from the macro processor, until all lines of the current macro definition have been read.

Repeating statements

Use the `REPT...ENDR` structure to assemble the same block of instructions a number of times. If `expr` evaluates to 0 nothing will be generated.

Use `REPTC` to assemble a block of instructions once for each character in a string. If the string contains a comma it should be enclosed in quotation marks.
Only double quotes have a special meaning and their only use is to enclose the characters to iterate over. Single quotes have no special meaning and are treated as any ordinary character.

Use `REPTI` to assemble a block of instructions once for each string in a series of strings. Strings containing commas should be enclosed in quotation marks.

**EXAMPLES**

This section gives examples of the different ways in which macros can make assembler programming easier.

**Coding in-line for efficiency**

In time-critical code it is often desirable to code routines in-line to avoid the overhead of a subroutine call and return. Macros provide a convenient way of doing this.

For example, the following subroutine outputs a 256-byte buffer to a port:

```assembly
EXTERN port
RSEG RAM
buffer DB 25
RSEG PROM
; Plays 256 bytes from buffer to port
play MOV #buffer,R4
MOV #256,R5
loop MOV @R4+,&port
INC R4
DEC R5
JNE loop
RET
END
```

The main program calls this routine as follows:

```assembly
doplay CALL play
```

```assembly
```

A430-2
Macro processing directives

For efficiency we can recode this as the following macro:

;Plays 256 bytes from buffer to port

```
play MACRO
LOCAL loop
MOV #buffer,R4
MOV #64,R5
loop MOV @R4+,&port
MOV @R4+,&port
MOV @R4+,&port
MOV @R4+,&port
DEC R5
JNE loop
ENDM
```

Note the use of `LOCAL` to make the label loop local to the macro; otherwise an error will be generated if the macro is used twice, as the loop label will already exist. To use in-line code the main program is then simply altered to:

doplay play

Using REPT and ENDR

The following example uses REPT to assemble a table of powers of 3:

```
NAME table
main ;Generate table of powers of 3
calc SET 1
REPT 8
DW calc
calc SET calc *3
ENDR
END main
```

It generates the following code:

```
1 00000000  NAME  table
2 00000000
3 00000000  main ;Generate table of powers of 3
4 00000001  calc  SET 1
5 00000000  REPT  8
6 00000000  DW   calc
7 00000000  calc  SET  calc *3
8 00000000  ENDR
8.1 00000000 0001  DW   calc
8.2 00000003  calc  SET  calc *3
8.3 00000002 0003  DW   calc
8.4 00000009  calc  SET  calc *3
8.5 00000004 0009  DW   calc
```
Using REPTC and REPTI

The following example assembles a series of calls to a subroutine `putc` for each character in a string:

```
EXTERN putc
prompt REPTC char,"Login:"
MOV 'char',r4
CALL putc
ENDR
```

It generates the following code:

```
MOV 'L',r4
CALL putc
MOV 'o',r4
CALL putc
MOV 'g',r4
CALL putc
MOV 'i',r4
CALL putc
MOV 'n',r4
CALL putc
MOV ':',r4
CALL putc
```

The following example uses REPTI to clear a number of memory locations:

```
REPTI zero,"R4","R5","R6"
MOV #0,zero
ENDR
```

It generates the following code:

```
MOV #0,R4
MOV #0,R5
MOV #0,R6
```
Listing control directives

Listing control directives

These directives provide control over the assembler list file.

<table>
<thead>
<tr>
<th>Directive</th>

LSTCOD{+|-}
LSTEXP{+|-}
LSTMAC{+|-}
LSTOUT{+|-}
LSTPAG{+|-}
LSTREP{+|-}
LSTXRF{+|-}
PAGE
PAGSIZ lines

**PARAMETERS**

columns    An absolute expression in the range 80 to 132, default is 80
lines      An absolute expression in the range 10 to 150, default is 44
DESCRIPTION

Turning the listing on or off
Use LSTOUT - to disable all list output except error messages. This directive overrides all other listing control directives. The default is LSTOUT+, which lists the output (if a list file was specified).

Listing conditional code and strings
Use LSTCND+ to force the assembler to list source code only for the parts of the assembly that are not disabled by conditional IF statements. The default setting is LSTCND-, which lists all source lines.

Use LSTCOD- to restrict the listing of output code to just the first line of code for a source line. The default setting is LSTCOD+, which lists more than one line of code for a source line, if needed; i.e. long ASCII strings will produce several lines of output. Code generation is not affected.

Controlling the listing of macros
Use LSTEXP- to disable the listing of macro-generated lines. The default is LSTEXP+, which lists all macro-generated lines.

Use LSTMAC+ to list macro definitions. The default is LSTMAC-, which disables the listing of macro definitions.

Controlling the listing of generated lines
Use LSTREP- to turn off the listing of lines generated by the directives REPT, REPTC, and REPTI. The default is LSTREP+, which lists the generated lines.

Generating a cross-reference table
Use LSTXRF+ to generate a cross-reference table at the end of the assembler list for the current module. The table shows values and line numbers, and the type of the symbol. The default is LSTXRF-, which does not give a cross-reference table.

Specifying the list file format
Use COL to set the number of columns per page of the assembler list. The default number of columns is 80.

Use PAGSIZ to set the number of printed lines per page of the assembler list. The default number of lines per page is 44.

Use LSTPAG+ to format the assembler output list into pages. The default is LSTPAG-, which gives a continuous listing.
Listing control directives

Use \texttt{PAGE} to generate a new page in the assembler list file if paging is active.

\textbf{EXAMPLES}

\textbf{Turning the listing on or off}

To disable the listing of a debugged section of program:

\begin{verbatim}
LSTOUT- ; Debugged section
LSTOUT+ ; Not yet debugged
\end{verbatim}

\textbf{Listing conditional code and strings}

The following example shows how \texttt{LSTCND+} hides a call to a subroutine that is disabled by an \texttt{IF} directive:

\begin{verbatim}
NAME lstcndtst
EXTERN print
RSEG prom
debugeq VAR 0
begin IF debug
CALL print
ENDIF
LSTCND+
begin2 IF debug
CALL print
ENDIF
END
\end{verbatim}

This will generate the following listing:

\begin{verbatim}
1 00000000  NAME lstcndtst
2 00000000  EXTERN print
3 00000000
4 00000000  RSEG CODE
5 00000000
6 00000000  debug VAR 0
7 00000000  begin IF debug
8 00000000  CALL print
9 00000000  ENDIF
10 00000000
11 00000000  LSTCND+
12 00000000  begin2 IF debug
\end{verbatim}
Assembler directives

The following example shows the effect of LSTCOD:

NAME    lstcodtst
EXTERN  print
RSEG    CONST
DC32    1,10,100,1000,10000

LSTCOD+
DC32    1,10,100,1000,10000

END

This will generate the following listing:

Controlling the listing of macros

The following example shows the effect of LSTMAC and LSTEXP:

dec2    MACRO  arg
DEC    arg
DEC    arg
ENDM

LSTMAC+

inc2    MACRO  arg
INC    arg
INC    arg
ENDM
Listing control directives

begin:
    dec2   R6
    LSTEXP-
    inc2   R7
    RET
    END    begin

This will produce the following output:

<table>
<thead>
<tr>
<th>Line</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>000000</td>
</tr>
<tr>
<td>6</td>
<td>000000</td>
</tr>
<tr>
<td>7</td>
<td>inc2</td>
</tr>
<tr>
<td>8</td>
<td>INC</td>
</tr>
<tr>
<td>9</td>
<td>arg</td>
</tr>
<tr>
<td>10</td>
<td>ENDM</td>
</tr>
<tr>
<td>11</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td></td>
</tr>
<tr>
<td>13</td>
<td>dec2</td>
</tr>
<tr>
<td>13.1</td>
<td>DEC</td>
</tr>
<tr>
<td>13.2</td>
<td>DEC</td>
</tr>
<tr>
<td>13.3</td>
<td>ENDM</td>
</tr>
<tr>
<td>14</td>
<td></td>
</tr>
<tr>
<td>15</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>inc2</td>
</tr>
<tr>
<td>17</td>
<td>RET</td>
</tr>
<tr>
<td>18</td>
<td>ENDM</td>
</tr>
</tbody>
</table>

Formatting listed output

The following example formats the output into pages of 66 lines each with 132 columns. The LSTPAG directive organizes the listing into pages, starting each module on a new page. The PAGE directive inserts additional page breaks.

```
PAGESIZ 66 ; Page size
COL 132
LSTPAG+
... 
ENDMOD
MODULE
...
PAGE
...
```
C-style preprocessor directives

The following C-language preprocessor directives are available:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#define</td>
<td>Assigns a value to a label.</td>
</tr>
<tr>
<td>#elif</td>
<td>Introduces a new condition in a #if...#endif block.</td>
</tr>
<tr>
<td>#else</td>
<td>Assembles instructions if a condition is false.</td>
</tr>
<tr>
<td>#endif</td>
<td>Ends a #if, #ifdef, or #ifndef block.</td>
</tr>
<tr>
<td>#error</td>
<td>Generates an error.</td>
</tr>
<tr>
<td>#if</td>
<td>Assembles instructions if a condition is true.</td>
</tr>
<tr>
<td>#ifdef</td>
<td>Assembles instructions if a symbol is defined.</td>
</tr>
<tr>
<td>#ifndef</td>
<td>Assembles instructions if a symbol is undefined.</td>
</tr>
<tr>
<td>#include</td>
<td>Includes a file.</td>
</tr>
<tr>
<td>#message</td>
<td>Generates a message on standard output.</td>
</tr>
<tr>
<td>#undef</td>
<td>Undefines a label.</td>
</tr>
</tbody>
</table>

Table 25: C-style preprocessor directives

SYNTAX

```
#define label text
#elif condition
#else
#endif
#error "message"
#if condition
#else ifdef label
#else ifndef label
#include {"filename" | <filename>}
#else message "message"
#else undef label
```

PARAMETERS

<table>
<thead>
<tr>
<th>condition</th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>An absolute expression</td>
</tr>
</tbody>
</table>

The expression must not contain forward or external references, and any non-zero value is considered as true.
C-style preprocessor directives

string1=string

The condition is true if string1 and string2 have the same length and contents.

string1<>string2

The condition is true if string1 and string2 have different length or contents.

filename  Name of file to be included.
label    Symbol to be defined, undefined, or tested.
message  Text to be displayed.
text     Value to be assigned.

DESCRIPTION

Defining and undefining labels

Use #define to define a temporary label.

#define label value

is similar to:

label VAR value

Use #undef to undefine a label; the effect is as if it had not been defined.

Conditional directives

Use the #if...#else...#elif...#endif directives to control the assembly process at assembly time. If the condition following the #if directive is not true, the subsequent instructions will not generate any code (i.e. it will not be assembled or syntax checked) until a #endif or #else directive is found.

All assembler directives (except for END) and file inclusion may be disabled by the conditional directives. Each #if directive must be terminated by a #endif directive. The #else directive is optional and, if used, it must be inside a #if...#endif block. #if...#endif and #if...#else...#elif...#endif blocks may be nested to any level.

Use #ifdef to assemble instructions up to the next #else or #endif directive only if a symbol is defined.

Use #ifndef to assemble instructions up to the next #else or #endif directive only if a symbol is undefined.
Including source files
Use `#include` to insert the contents of a file into the source file at a specified point.
`#include "filename"` searches the following directories in the specified order:
1. The source file directory.
2. The directories specified by the `-I` option, or options.
3. The current directory.
`#include <filename>` searches the following directories in the specified order:
1. The directories specified by the `-I` option, or options.
2. The current directory.

Displaying errors
Use `#error` to force the assembler to generate an error, such as in a user-defined test.

Comments in define statements
If you make a comment within a define statement, use the C/EC++ comment delimiters `/* ... */`, alternatively `//`.
The following example illustrates some problems that may occur when assembler comments are used in the C-style preprocessor:

```
#define five 5 ; this comment is not ok
#define six 6   // this comment is ok
#define seven 7 /* this comment is ok */

MOV    five,R5 ; syntax error!
; expands to "MOV    5 ; this comment is not ok,R5"

MOV    six+seven,R5 ; ok
; expands to "MOV    6+7,R5"
```
EXAMPLES

Using conditional directives

The following example defines the variables `tweek` and `adjust`. It then tests to see if `tweek` is defined. If it is defined, `R4` is set to 7, 12, or 30 depending on the value of `adjust`.

```asm
EXTERN    input
#define tweek     1
#define adjust    3
#ifdef tweek
#if adjust=1
ADD   #7,R4
#elif adjust=2
ADD   #12,R4
#elif adjust=3
ADD   #30,R4
#endif
#endif /*ifdef tweek*/
MOV   R4,input
RET
END
```

This will generate the following listing:

```
1  000000                        EXTERN    input
2  000000              #define tweek     1
3  000000              #define adjust    3
4  000000
5  000000
6  000000              #ifdef tweek
7  000000              #if adjust=1
9  000000              #elif adjust=2
11  000000              #elif adjust=3
12  000000 34501E00               ADD   #30,R4
13  000004              #endif
14  000004              #endif /*ifdef tweek*/
15  000004 8044....               MOV   R4,input
16  000000 3041                   RET
17  00000A
18  00000A                        END
```
Including a source file

The following example uses `#include` to include a file defining a macro into the source file, for instance, `macros.s43`:

```assembly
xch   MACRO   a,b
      PUSH    a
      MOV     a,b
      POP     b
      ENDM
```

The macro definitions can then be included, using `#include`, as in the following example:

```assembly
NAME   include

; standard macro definitions
#include "macros.s43"

; program
main:  xch     R6,R7
        RET
END main
```

Data definition or allocation directives

These directives define values or reserve memory. The column `Alias` in the following table shows the Texas Instruments directive that corresponds to the IAR Systems directive:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Alias</th>
<th>Description</th>
<th>Expression restrictions</th>
</tr>
</thead>
<tbody>

Table 26: Data definition or allocation directives (Continued)

SYNTAX

DC8 expr [,expr] ...
DC16 expr [,expr] ...
DC32 expr [,expr] ...
DC64 expr [,expr] ...
DF32 value [,value] ...
DF64 value [,value] ...
.float value [,value] ...
DS8 size_expr
DS16 size_expr
DS32 size_expr
DS64 size_expr
.float value [,value] ...

PARAMETERS

expr A valid absolute, relocatable, or external expression, or an ASCII string. ASCII strings will be zero filled to a multiple of the data size implied by the directive. Double-quoted strings will be zero-terminated.

size_expr The size in bytes; an expression that can be evaluated at assembly time.

value A valid absolute expression or a floating-point constant.
DESCRIPTIONS

Use the data definition and allocation directives according to the following table; it shows which directives reserve and initialize memory space or reserve uninitialized memory space, and their size.

<table>
<thead>
<tr>
<th>Size</th>
<th>Reserve and initialize memory</th>
<th>Reserve uninitialized memory</th>
</tr>
</thead>
<tbody>

Table 27: Using data definition or allocation directives

EXAMPLES

Generating lookup table

The following example generates a lookup table of addresses to routines:

```assembly
NAME table
RSEG CONST
table DW addsubr, subsubr, clrsubr
RSEG CODE
addsubr ADD R4, R5
RET
subsubr SUB R4, R5
RET
clrsubr CLR R4
RET
END
```

Defining strings

To define a string:

```assembly
mymsg  DC8 'Please enter your name'
```

To define a string which includes a trailing zero:

```assembly
myCstr  DC8 "This is a string."
```

To include a single quote in a string, enter it twice; for example:

```assembly
errmsg  DC8 'Don''t understand!'```

Reserving space

To reserve space for 0xA bytes:

```
table DS8 0xA
```

## Assembler control directives

These directives provide control over the operation of the assembler.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>Includes a file.</td>
</tr>
<tr>
<td>/<em>...</em>/</td>
<td>C-style comment delimiter.</td>
</tr>
<tr>
<td>//</td>
<td>C++-style comment delimiter.</td>
</tr>
<tr>
<td>CASEOFF</td>
<td>Disables case sensitivity.</td>
</tr>
<tr>
<td>CASEON</td>
<td>Enables case sensitivity.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Sets the default base on all numeric values. Default base is 10.</td>
</tr>
</tbody>
</table>

### SYNTAX

```
$filename
/*comment*/
//comment
CASEOFF
CASEON
RADIX expr
```

### PARAMETERS

- `comment`: Comment ignored by the assembler.
- `expr`: Default base; default 10 (decimal).
- `filename`: Name of file to be included. The $ character must be the first character on the line.

### DESCRIPTION

- Use $ to insert the contents of a file into the source file at a specified point.
- Use /*...*/ to comment sections of the assembler listing.
- Use // to mark the rest of the line as comment.
- Use RADIX to set the default base for constants.
Controlling case sensitivity

Use CASEON or CASEOFF to turn on or off case sensitivity for user-defined symbols. By default case sensitivity is off.

When CASEOFF is active all symbols are stored in upper case, and all symbols used by XLINK should be written in upper case in the XLINK definition file.

EXAMPLES

Including a source file

The following example uses $ (program location counter) to include a file defining macros into the source file. For instance, in mymacros.s43:

```assembly
times2 MACRO reg
       RLA reg
       ENDM

LSTMAC+

div2 MACRO reg
       RRA reg
       ENDM
```

The macro definitions can be included with the $ directive, as in:

```assembly
NAME    include

; standard macro definitions
$mymacros.s43

; program
main    MOV     #123,R4
       mySubMacro #2,R4
       RET
       END main
```

Defining comments

The following example shows how /*...*/ can be used for a multi-line comment:

```assembly
/*
Program to read serial input.
Version 3: 19.12.01
Author: mjp
*/
```
Changing the base

To set the default base to 16:

```assembly
RADIX 16
LDI #12,R3
```

The immediate argument will then be interpreted as \texttt{H'12}.

To change the base from 16 to 10, \texttt{expr} must be written in hexadecimal format, for example:

```assembly
RADIX 0x10
```

Controlling case sensitivity

When \texttt{CASEOFF} is set, \texttt{label} and \texttt{LABEL} are identical in the following example:

```assembly
label NOP       ; Stored as "LABEL"
JMP LABEL
```

The following will generate a duplicate label error:

```assembly
CASEOFF
label NOP
LABEL NOP       ; Error, "LABEL" already defined
```

Call frame information directives

These directives allow backtrace information to be defined in the assembler source code. The benefit is that you will be able to use the call frame stack when debugging assembler code.

PARAMETERS

bits The size of the resource in bits.
cell The name of a frame cell.
cfa The name of a CFA (canonical frame address).
Assembler directives

**DESCRIPTIONS**

The Call Frame Information directives (CFI directives) are an extension to the debugging format of the IAR C-SPY Debugger. The CFI directives are used for defining the backtrace information for the instructions in a program. The compiler normally generates this information, but for library functions and other code written purely in assembler language, backtrace information has to be added if you want to use the call frame stack in the debugger.

- **cfiexpr**: A CFI expression (see CFI expressions, page 87).
- **codealignfactor**: The smallest factor of all instruction sizes. Each CFI directive for a data block must be placed according to this alignment. 1 is the default and can always be used, but a larger value will shrink the produced backtrace information in size. The possible range is 1–256.
- **commonblock**: The name of a previously defined common block.
- **constant**: A constant value or an assembler expression that can be evaluated to a constant value.
- **dataalignfactor**: The smallest factor of all frame sizes. If the stack grows towards higher addresses, the factor is negative; if it grows towards lower addresses, the factor is positive. 1 is the default, but a larger value will shrink the produced backtrace information in size. The possible ranges are -256 – -1 and 1 – 256.
- **label**: A function label.
- **name**: The name of the block.
- **namesblock**: The name of a previously defined names block.
- **offset**: The offset relative the CFA. An integer with an optional sign.
- **part**: A part of a composite resource. The name of a previously declared resource.
- **resource**: The name of a resource.
- **segment**: The name of a segment.
- **size**: The size of the frame cell in bytes.
- **type**: The memory type, such as CODE, CONST or DATA. In addition, any of the memory types supported by the IAR XLINK Linker. It is used solely for the purpose of denoting an address space.
The backtrace information is used to keep track of the contents of resources, such as registers or memory cells, in the assembler code. This information is used by the IAR C-SPY Debugger to go “back” in the call stack and show the correct values of registers or other resources before entering the function. In contrast with traditional approaches, this permits the debugger to run at full speed until it reaches a breakpoint, stop at the breakpoint, and retrieve backtrace information at that point in the program. The information can then be used to compute the contents of the resources in any of the calling functions—assuming they have call frame information as well.

Backtrace rows and columns
At each location in the program where it is possible for the debugger to break execution, there is a backtrace row. Each backtrace row consists of a set of columns, where each column represents an item that should be tracked. There are three kinds of columns:

- The resource columns keep track of where the original value of a resource can be found.
- The canonical frame address columns (CFA columns) keep track of the top of the function frames.
- The return address column keeps track of the location of the return address.

There is always exactly one return address column and usually only one CFA column, although there may be more than one.

Defining a names block
A names block is used to declare the resources available for a processor. Inside the names block, all resources that can be tracked are defined.

Start and end a names block with the directives:

```
CFI NAMES name
CFI ENDNAMES name
```

where name is the name of the block.

Only one names block can be open at a time.

Inside a names block, four different kinds of declarations may appear: a resource declaration, a stack frame declaration, a static overlay frame declaration, or a base address declaration:

- To declare a resource, use one of the directives:

```
CFI RESOURCE resource : bits
CFI VIRTUALRESOURCE resource : bits
```
Assembler directives

The parameters are the name of the resource and the size of the resource in bits. A virtual resource is a logical concept, in contrast to a "physical" resource such as a processor register. Virtual resources are usually used for the return address.

More than one resource can be declared by separating them with commas.

A resource may also be a composite resource, made up of at least two parts. To declare the composition of a composite resource, use the directive:

\[
\text{CFI RESOURCEPARTS resource part, part, ...}
\]

The parts are separated with commas. The resource and its parts must have been previously declared as resources, as described above.

- To declare a stack frame CFA, use the directive:

\[
\text{CFI STACKFRAME cfa resource type}
\]

The parameters are the name of the stack frame CFA, the name of the associated resource (the stack pointer), and the segment type (to get the address space). More than one stack frame CFA can be declared by separating them with commas.

When going "back" in the call stack, the value of the stack frame CFA is copied into the associated stack pointer resource to get a correct value for the previous function frame.

- To declare a static overlay frame CFA, use the directive:

\[
\text{CFI STATICOVERLAYFRAME cfa segment}
\]

The parameters are the name of the CFA and the name of the segment where the static overlay for the function is located. More than one static overlay frame CFA can be declared by separating them with commas.

- To declare a base address CFA, use the directive:

\[
\text{CFI BASEADDRESS cfa type}
\]

The parameters are the name of the CFA and the segment type. More than one base address CFA can be declared by separating them with commas.

A base address CFA is used to conveniently handle a CFA. In contrast to the stack frame CFA, there is no associated stack pointer resource to restore.

Extending a names block

In some special cases you have to extend an existing names block with new resources. This occurs whenever there are routines that manipulate call frames other than their own, such as routines for handling, entering, and leaving C or Embedded C++ functions; these routines manipulate the caller’s frame. Extended names blocks are normally used only by compiler developers.
Extend an existing names block with the directive:

```
CFI NAMES name EXTENDS namesblock
```

where `namesblock` is the name of the existing names block and `name` is the name of the new extended block. The extended block must end with the directive:

```
CFI ENDNAMES name
```

### Defining a common block

The **common block** is used for declaring the initial contents of all tracked resources. Normally, there is one common block for each calling convention used.

Start a common block with the directive:

```
CFI COMMON name USING namesblock
```

where `name` is the name of the new block and `namesblock` is the name of a previously defined names block.

Declare the return address column with the directive:

```
CFI RETURNADDRESS resource type
```

where `resource` is a resource defined in `namesblock` and `type` is the segment type. You have to declare the return address column for the common block.

End a common block with the directive:

```
CFI ENDCOMMON name
```

where `name` is the name used to start the common block.

Inside a common block you can declare the initial value of a CFA or a resource by using the directives listed last in **Common block directives**, page 80. For more information on these directives, see **Simple rules**, page 85, and **CFI expressions**, page 87.

### Extending a common block

Since you can extend a names block with new resources, it is necessary to have a mechanism for describing the initial values of these new resources. For this reason, it is also possible to extend common blocks, effectively declaring the initial values of the extra resources while including the declarations of another common block. Just as in the case of extended names blocks, extended common blocks are normally only used by compiler developers.

Extend an existing common block with the directive:

```
CFI COMMON name EXTENDS commonblock USING namesblock
```
where \textit{name} is the name of the new extended block, \textit{commonblock} is the name of the existing common block, and \textit{namesblock} is the name of a previously defined names block. The extended block must end with the directive:

\texttt{CFI ENDCOMMON name}

**Defining a data block**

The \textit{data block} contains the actual tracking information for one continuous piece of code. No segment control directive may appear inside a data block.

Start a data block with the directive:

\texttt{CFI BLOCK name USING commonblock}

where \textit{name} is the name of the new block and \textit{commonblock} is the name of a previously defined common block.

If the piece of code is part of a defined function, specify the name of the function with the directive:

\texttt{CFI FUNCTION label}

where \textit{label} is the code label starting the function.

If the piece of code is not part of a function, specify this with the directive:

\texttt{CFI NOFUNCTION}

End a data block with the directive:

\texttt{CFI ENDBLOCK name}

where \textit{name} is the name used to start the data block.

Inside a data block you may manipulate the values of the columns by using the directives listed last in \textit{Data block directives}, page 80. For more information on these directives, see \textit{Simple rules}, page 85, and \textit{CFI expressions}, page 87.

**SIMPLE RULES**

To describe the tracking information for individual columns, there is a set of simple rules with specialized syntax:

\begin{verbatim}
CFI cfa { NOTUSED | USED }
CFI cfa { resource | resource + constant | resource - constant }
CFI resource { UNDEFINED | SAMEVALUE | CONCAT }
CFI resource { resource | FRAME(cfa, offset) }
\end{verbatim}

These simple rules can be used both in common blocks to describe the initial information for resources and CFAs, and inside data blocks to describe changes to the information for resources or CFAs.
In those rare cases where the descriptive power of the simple rules are not enough, a full CFI expression can be used to describe the information (see CFI expressions, page 87). However, whenever possible, you should always use a simple rule instead of a CFI expression.

There are two different sets of simple rules: one for resources and one for CFAs.

Simple rules for resources

The rules for resources conceptually describe where to find a resource when going back one call frame. For this reason, the item following the resource name in a CFI directive is referred to as the location of the resource.

To declare that a tracked resource is restored, that is, already correctly located, use SAMEVALUE as the location. Conceptually, this declares that the resource does not have to be restored since it already contains the correct value. For example, to declare that a register REG is restored to the same value, use the directive:

```c
CFI REG SAMEVALUE
```

To declare that a resource is not tracked, use UNDEFINED as location. Conceptually, this declares that the resource does not have to be restored (when going back one call frame) since it is not tracked. Usually it is only meaningful to use it to declare the initial location of a resource. For example, to declare that REG is a scratch register and does not have to be restored, use the directive:

```c
CFI REG UNDEFINED
```

To declare that a resource is temporarily stored in another resource, use the resource name as its location. For example, to declare that a register REG1 is temporarily located in a register REG2 (and should be restored from that register), use the directive:

```c
CFI REG1 REG2
```

To declare that a resource is currently located somewhere on the stack, use FRAME(cfa, offset) as location for the resource, where cfa is the CFA identifier to use as “frame pointer” and offset is an offset relative the CFA. For example, to declare that a register REG is located at offset -4 counting from the frame pointer CFA_SP, use the directive:

```c
CFI REG FRAME(CFA_SP,-4)
```

For a composite resource there is one additional location, CONCAT, which declares that the location of the resource can be found by concatenating the resource parts for the composite resource. For example, consider a composite resource RET with resource parts RETLO and RETHI. To declare that the value of RET can be found by investigating and concatenating the resource parts, use the directive:

```c
CFI RET CONCAT
```
This requires that at least one of the resource parts has a definition, using the rules described above.

**Simple rules for CFAs**

In contrast with the rules for resources, the rules for CFAs describe the address of the beginning of the call frame. The call frame often includes the return address pushed by the subroutine calling instruction. The CFA rules describe how to compute the address to the beginning of the current call frame. There are two different forms of CFAs, stack frames and static overlay frames, each declared in the associated names block. See *Names block directives*, page 79.

Each stack frame CFA is associated with a resource, such as the stack pointer. When going back one call frame the associated resource is restored to the current CFA. For stack frame CFAs there are two possible simple rules: an offset from a resource (not necessarily the resource associated with the stack frame CFA) or `NOTUSED`.

To declare that a CFA is not used, and that the associated resource should be tracked as a normal resource, use `NOTUSED` as the address of the CFA. For example, to declare that the CFA with the name `CFA_SP` is not used in this code block, use the directive:

```
CFI CFA_SP NOTUSED
```

To declare that a CFA has an address that is offset relative the value of a resource, specify the resource and the offset. For example, to declare that the CFA with the name `CFA_SP` can be obtained by adding 4 to the value of the `SP` resource, use the directive:

```
CFI CFA_SP SP + 4
```

For static overlay frame CFAs, there are only two possible declarations inside common and data blocks: `USED` and `NOTUSED`.

**CFI expressions**

Call Frame Information expressions (CFI expressions) can be used when the descriptive power of the simple rules for resources and CFAs is not enough. However, you should always use a simple rule when one is available.

CFI expressions consist of operands and operators. Only the operators described below are allowed in a CFI expression. In most cases, they have an equivalent operator in the regular assembler expressions.

In the operand descriptions, `cfiexpr` denotes one of the following:

- A CFI operator with operands
- A numeric constant
- A CFA name
- A resource name.
Unary operators

Table 32: Ternary operators in CFI expressions

**EXAMPLE**

The following is a generic example and not an example specific to the MSP430 microcontroller. This will simplify the example and clarify the usage of the CFI directives. A target-specific example can be obtained by generating assembler output when compiling a C source file.

Consider a generic processor with a stack pointer `SR`, and two registers `R4` and `R5`. Register `R4` will be used as a scratch register (the register is destroyed by the function call), whereas register `R5` has to be restored after the function call. For reasons of simplicity, all instructions, registers, and addresses will have a width of 16 bits.
Consider the following short code sample with the corresponding backtrace rows and columns. At entry, assume that the stack contains a 16-bit return address. The stack grows from high addresses towards zero. The CFA denotes the top of the call frame, that is, the value of the stack pointer after returning from the function.

<table>
<thead>
<tr>
<th>Address</th>
<th>CFA</th>
<th>SP</th>
<th>R4</th>
<th>R5</th>
<th>RET</th>
<th>Assembler code</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>SP + 2</td>
<td>—</td>
<td>SAME</td>
<td>CFA - 2</td>
<td>func1: PUSH R5</td>
<td></td>
</tr>
<tr>
<td>0002</td>
<td>SP + 4</td>
<td>CFA - 4</td>
<td></td>
<td></td>
<td>MOV #4, R5</td>
<td></td>
</tr>
<tr>
<td>0004</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>CALL func2</td>
<td></td>
</tr>
<tr>
<td>0006</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>POP R4</td>
<td></td>
</tr>
<tr>
<td>0008</td>
<td>SP + 2</td>
<td>R4</td>
<td></td>
<td></td>
<td>MOV R4, R5</td>
<td></td>
</tr>
<tr>
<td>000A</td>
<td></td>
<td>SAME</td>
<td></td>
<td></td>
<td>RET</td>
<td></td>
</tr>
</tbody>
</table>

Table 33: Code sample with backtrace rows and columns

Each backtrace row describes the state of the tracked resources before the execution of the instruction. As an example, for the MOV R4, R5 instruction the original value of the R5 register is located in the R4 register and the top of the function frame (the CFA column) is $SP + 2$. The backtrace row at address 0000 is the initial row and the result of the calling convention used for the function.

The SP column is empty since the CFA is defined in terms of the stack pointer. The RET column is the return address column—that is, the location of the return address. The R4 column has a ‘—’ in the first line to indicate that the value of R4 is undefined and does not need to be restored on exit from the function. The R5 column has SAME in the initial row to indicate that the value of the R5 register will be restored to the same value it already has.

**Defining the names block**

The names block for the small example above would be:

```assembly
CFI NAMES trivialNames
CFI RESOURCE SP:16, R4:16, R5:16
CFI STACKFRAME CFA SP DATA

;; The virtual resource for the return address column
CFI VIRTUALRESOURCE RET:16
CFI ENDNAMES trivialNames
```
Defining the common block

The common block for the simple example above would be:

CFI COMMON trivialCommon USING trivialNames
CFI RETURNADDRESS RET DATA
CFI CPA SP + 2
CFI R4 UNDEFINED
CFI R5 SAMEVALUE
CFI RET FRAME(CFA,-2) ; Offset -2 from top of frame
CFI ENDCOMMON trivialCommon

Note: SP may not be changed using a CFI directive since it is the resource associated with CFA.

Defining the data block

Continuing the simple example, the data block would be:

RSEG CODE:CODE
CFI BLOCK func1block USING trivialCommon
CFI FUNCTION func1
func1:
  PUSH R5
  CFI CPA SP + 4
  CFI R5 FRAME(CFA,-4)
  MOV #4,R5
  CALL func2
  POP R4
  CFI R5 R4
  CFI CPA SP + 2
  MOV R4,R5
  CFI R5 SAMEVALUE
  RET
  CFI ENDBLOCK func1block

Note that the CFI directives are placed after the instruction that affects the backtrace information.
Call frame information directives
Diagnostics

This chapter describes the format of the diagnostic messages and explains how diagnostic messages are divided into different levels of severity.

Message format

All diagnostic messages are issued as complete, self-explanatory messages. A typical diagnostic message from the assembler is produced in the form:

filename,linenumber level[tag]: message

where filename is the name of the source file in which the error was encountered; linenumber is the line number at which the assembler detected the error; level is the level of severity of the diagnostic; tag is a unique tag that identifies the diagnostic message; message is a self-explanatory message, possibly several lines long.

Diagnostic messages are displayed on the screen, as well as printed in the optional list file.

In addition, you can find all messages specific to the MSP430 Assembler in the readme file a430_msg.htm.

Severity levels

The diagnostics are divided into different levels of severity:

**Warning**

A diagnostic message that is produced when the assembler finds a programming error or omission which is of concern but not so severe as to prevent the completion of compilation. Warnings can be disabled by use of the command-line option -w, see page 21.

**Error**

A diagnostic message that is produced when the assembler has found a construct which clearly violates the language rules, such that code cannot be produced.
Severity levels

Fatal error
A diagnostic message that is produced when the assembler has found a condition that not only prevents code generation, but which makes further processing of the source code pointless. After the diagnostic has been issued, compilation terminates.

INTERNAL ERROR
An internal error is a diagnostic message that signals that there has been a serious and unexpected failure due to a fault in the assembler. It is produced using the following form:

Internal error: message

where *message* is an explanatory message. If internal errors occur, they should be reported to your software distributor or IAR Technical Support. Please include information enough to reproduce the problem. This would typically include:

- The product name
- The version number of the assembler, which can be seen in the header of the list files generated by the assembler
- Your license number
- The exact internal error message text
- The source file of the program that generated the internal error
- A list of the options that were used when the internal error occurred.
